A

al, M., physiological action of Collinsonia canadensis, 39

bano, Peter of (Mr. C. E. A. Clayton), 1886

battoir, municipal, proposed for Portsmouth, 1872; of Belfast, 1539; (Parliamentary question), 1570; public, of Birmingham, and meat market, 1532; slaughter-houses of Dublin, 1180

battoirs renewal of lease, at Liverpool, 679; undesirable proximity to Liverpool Royal Infirmary, 524; public, provision of, in Scotland (leading article), 1639

bey Sanatorium for Pulmonary Tuberculosis, Belfast, 1037

bdomen, excision of pad of fat from wall of, [illegible]; injuries of, diagnosis and treatment, [illegible]; and pelves, examination of, during pregnancy, 1417; safe method of opening, [illegible]; some conditions of, and appendicitis diagnosed by x rays (Sir W. H. Bennett), [illegible]; wound in, suture and retractor forceps, [illegible]

bdominal aorta, occlusion of (Dr. C. H. Cattle), 1691

el's Laboratory Handbook of Bacteriology, [illegible] edition (translation by Dr. M. H. Gordon) (review), 165

erdeen, cerebro-spinal meningitis in, 134; hospital abuse in, 630; medical appointments, 1244; spitting on pavements in, 974; town council and street accidents, 816; University of, 752; honorary degree at, 13; pass lists, 1184; (University) Studies in Pathology written by Alumni to Celebrate the Quatercentenary and the Quartercentenary of the Chair of Pathology, edited by Dr. W. Bulloch, 1906 (review), 684; water-supply of, important report, 1180 (see also Morningfield Hospital)

erdeen City Hospital, extension of, 1516; proposed extension of, 1447

erdeen Dispensary, annual meeting, 896

erdeen Royal Infirmary, annual report, 599; donation from Lord Mount-Stephen, 1659; Hospital Sunday, 193

erdeen University Medical Society, 680

ortion, with abscess of thyroid gland, following perforative appendicitis in pregnancy (Mr. H. S. Pendlebury), 1007

raham, Dr. P. S., baldness caused by x rays in ringworm, 163; favus in a mouse, 1003

rahams, Dr. B., obituary, 1859

ram, Dr. J. H., and Paul, Mr. F. T., colloid cancer of stomach in a boy, 720

rams, M. P., and Widal, M. F., diagnosis of cancer in the central nervous system by lumbar puncture, 1093

Abscess, acute, method of obtaining rapid healing in cases of, 13, 46; appendicular, 430; appendicular, containing a pin, 1205; appendicular, simulated by sarcoma of right os innominatum (Dr. E. H. R. Harries), 1770; of cerebellum, unusual case in boy, 496; pulmonary, basal, 631; pulmonary, in left infra-scapular region, 292; subphrenic, 104, 159; subphrenic, paravertebral triangle of Grocco in, 172; temporo-sphenoidal, 644; of thyroid gland and abortion following perforative appendicitis in pregnancy (Mr. H. S. Pendlebury), 1007; tropical, of liver (Dr. T. R. Bradshaw), 146

Abstainers, Medical International Society of, 1727

Academic proletariat, 1224

Accessory sinuses, relations to eye, 1656; topography of, shown by x ray photographs, 1656; transillumination of, 1656

Accident ambulance wagon in the Rhondda, 197

Accident as cause of hernia?, in compensation case, 175

Accidents, industrial, in Hungary in 1907, 602; non-fatal, investigation of (Parliamentary question), 828

Accra, plague at, 248

Acetone, test for, exhibited, 1014

Acetone bodies, 912

Acetonuria, post-anæsthetic, 914

Achert, Dr. R. E., protracted use of digitalis, 1619

Achondroplasia, Cæsarean section in subject of, 721

Acid intoxication following administration of chloroform (Dr. H. Thorp), 623; following ethyl chloride anæsthesia (Dr. H. B. Cunningham), 284; in pregnancy, 637; pathology of (Dr. F. A. Bainbridge), 911

Acidity of urine (Mr. F. A. Watkins), 1766

Acne rosacea, 1518

Acrania, and imperfect development (Dr. A. Yule), 154

Acranial fœtus, two cases (Dr. J. Pirie), 100

Acromegaly (spurious (?)), 562; with exophthalmic goitre, 1203

Actinomycosis of cheek and glands of neck, 105; of the jaw, 24; case after two scraping operations, 105

Adam, Dr. J., pathology and treatment of atrophic rhinitis, 1419; severe spasmodic contraction of a finger cured by stretching the median nerve, 287

Adami, Prof. J. G., subinfection, 1568

Adams, Mr. P. E. H., epidemic of conjunctivitis due to pneumococcus, 1843

Adamson, Dr. H. G., diphtheria of the skin, 677; Skin Affections of Childhood, with Special Reference to those of more Common Occurrence and their Diagnosis and Treatment, 1907 (review), 1777

Addison's disease, death from symptoms of, in case of leucoderma, 1412; and pregnancy, 1393

Adelaide Children's Hospital, 65

Adeno-carcinoma corporis uteri, 1213

Adenoids, effect of open windows upon, 676, 1176; and open windows, 812; prevalence of, cause, 252, 454; relation of, to palatal deformities, 443

Adenoma (diffuse), occurring in fibroid uteri, 23; of thyroid, case of acute suppuration in, due to the bacillus typhosus (Dr. F. G. Melandri and Mr. T. P. Legg), 228

Adolescence, changes in the heart during (T. E. H. Williams), 967

Adrenalin in treatment of osteomalacia, 1183

"Adriatic," ventilation of, 1442

Adulteration of milk, justices' attitude on, 1457

Adults, *congenital stenosis of pylorus in, 1772*; defensive arrangements of body as illustrated by incidence of disease in (Sir W. W. Cheyne), 1816

Advancement operation (Worth's), 1305, 1368

Advertisement, indecent, 1596, 1735, 1892; medical, instance of, 139; objectionable, 907; unjustifiable, apology for, 1506

Advertisements, indecent, evidence respecting tendered to joint Parliamentary Committee, 1889

Æsculapius, serpent of, and snake-worship, 1023

Affleck, Dr. J. O., honorary degree to be conferred on, 526

Afforestation, 1090

Africa, pygmy and negro races of (Dr. F. C. Shrubsall), 1060, 1133; South-West, destruction of mosquitoes in, 1517; Medical Staff appointmentss, 1411; (see West African Medical Service)

After-care Association, 271; annual meeting, 473

After-cure for sanatorium patients, 1805

After-health of University oarsmen, 1089

Age in relation to prospect of recovery after surgical operations, 1518

Aged, Home of Rest for, in France, 1885

Agriculture, risks of arsenic in, 527

Aickin, Dr. W., obituary, 1246

Aikens, Charlotte A., Hospital Training School Methods and the Head Nurse, 1907 (review), 1166

Ailments, Common (Minor Medicine: Treatise on Common Ailments) (Dr. W. E. Wynter) (review), 866

Air, fresh, zeal for, 1880; impurities in, 1093; mechanical separation of oxygen from, 1783; subcutaneous injections of, in treatment of sciatica, 567; liquid, effect of, upon the graftable cancer of mice (Prof. J. E. Salvin-Moore and Dr. J. O. W. Barratt), 227

Air passages (upper), general treatment of local diseases of, 1445; upper, therapeutic value of x rays and radium, 1656

"Air-way," artificial, for use during anæsthetisation (Dr. F. W. Hewitt), 490
Aked and Aked, Messrs., question of medical defence, 1872
Alabone treatment, 139
Alberta, University of, date of opening, 1376
Albion Magazine (review), 649
Albrecht, Dr., successful case of Talma's operation, 1311
Albuminuria in renal tuberculosis, 916
Alcohol, consumption of, in France, 1803; effect on bacillus of enteric fever, 1518; and mental disease, 789; Side Lights on, and its Action on Human Organism (Medicus Abstinens) (review), 1846; sudden deprivation of, in delirium tremens, 39; treatment of pneumonia and enteric fever by, 442; and tuberculosis in Ireland, 474
Alcoholism, causes and treatment, 128; causing neuritis, 163; pathology of, 941; prominent factor in production of arterio-sclerosis, 1450
Alexander, Mr. F. W., electrolytically produced fluids containing hypochlorites, manufacture, rationale and chemistry of process for securing stability, 157
Alexandra Hospital, Montreal, 62
Alexandra Military Hospital, Portsmouth 258
Alexine, 433
Alford, Dr. H. J., appointed medical inspector of school children at Taunton, 249
Algeciras and its climate, 446
Algeria, sale of quinine in, 1037
Alimentary canal, of child, 15 months old, needle in, 189; diseases of, 1584; diverticula of, 860; relation of entozoa to mucous lining of, 1938
Alkaline earths, salts of, affecting coagulability of blood (Dr. J. B. Nias), 96
Allan, Dr. F. J., telephone call office as factor in spread of disease, 1862
Allbutt, Dr. T. C., and Rolleston, Dr. H. D., A System of Medicine by Many Writers, Vol. III., 1907 (review), 26
Allen, Dr. R. W., The Opsonic Method of Treatment: A Short Compendium for General Practitioners, Students, and Others, 1907 (review), 648
Allingham, Mr. W., obituary, 444, 530
Almoners, appointment of, to check out-patient abuse of hospitals, 620
Aloin (gelatin-coated) and phenolphthalein compound pill, 1778
Amalgamation proposed for Berlin medical societies, 1114
Ambulance, class in Crewe, 750; in the Rhondda, 197; lectures, St. John and St. Andrew (Parliamentary question), 826; metropolitan street service, 444; motor, in Rangoon, 1665; proposed draught of, by dogs, 1037; service at jubilee pageant in Vienna, 1857; system of New York, centralisation proposed, 63; (see also Dogs, First-aid, Horse); St. Andrews ambulance classes, International First Aid Congress, Motor ambulance)
America, "local hospitals" in, 611
American Practice of Surgery, edited by Dr. J. H. Bryant and Dr. A. H. Buck, vol. iii. (review), 1628
America, sanitary triumph of, in Panama (Mr. J. G. Leigh), 1646
Amnesia, case exhibited, 1418
Amputation of tabetic or trophic foot, 104; interscapulo-thoracic, 1080
Amyl (see Nitrite of amyl)
Anæmia, cardiac symptoms in, 1450; cerebral, and its ocular complications, 942; pernicious, with enlargement of spleen, 1209; splenic, aspects of (Dr. G. A. Gibson), 850
Anæsthesia, acetonuria following, 914; v. analgesia in obstetrics, 1213; v. analgesia in obstetrics and gynæcology (Sir W. J. Sinclair), 1541; deaths during, 697, 675, 1033, 1369, 1575; from anæsthetist's point of view, 1173; vomiting after, 291-2; (ethyl chloride) followed by acid intoxication (Dr. H. H. B. Cunningham), 284; general production by combination of scopolamine and morphine, 1721; (local) in minor surgery, 1709; (local) of extremities, new method of producing, 1721; lumbar (leading article), 870; spinal, 937, 1114, 1517; (surgical) coroner's inquests upon deaths in, 1106, 1304
Anæsthetic, responsibility for, 454; (general), clinical employment of ethyl chloride as, 1310
Anæsthetics, administration of (Parliamentary question), 1043, 1810; choice and administration of, 1513; compulsory instruction in use of (leading article), 1563; deaths under, 253, 1234; (Dr. F. J. Waldo), 851; deaths under, observations of Mr. J. Troutbeck, 1293; Parliamentary question, 636, 1353; legal responsibility and (Dr. D. W. Buxton), 151; (general) influence on blood, 268; improved "ideal" inhaler for, 297; post-mortem examinations in cases of death under, 1003-1012; proposition that instruction in, be made compulsory, 1009; sudden death under, analysis of 74 cases, 567
Anæsthetisation, artificial "air-way" for use during (Dr. F. W. Hewitt), 490
Anæsthetists, legal liability of, 1008, 1167; discussion on, 1003-1012; legal responsibility of (Dr. D. W. Buxton), 151; (leading article), 169
Analgesia v. anæsthesia in obstetrics, 1213; in obstetrics and gynæcology (Sir W. J. Sinclair), 1541; by intraspinal injection of stovaine, report on 50 cases (Mr. L. H. McGavin), 1058; present state of, 1555
Analgesic balm, 1778
Analysing creamery milk in county Derry, 1374

ANALYTICAL RECORDS FROM THE LANCET LABORATORY.—Alexine, 433—Alkuris Table Water, 434—Analgesic balm, 1788—Cognac Brandies, 31—Coryfin, 1778—Cyllin obstetricant lubricant, 1779—"Dry Sack"; Eustace Miles Food Preparations, 433—Fermenlactyl Tablets, 650—Formamint, 433—Formathol; Giesshübler (Mattoni's); Gluten Bread, 650—Gelatin-coated Aloin and Phenol-phthalein Compound Pill; Genuine Hollands; Hemisine, 1778—Irish Whisky, 433—Jamaica Tea; Marmite (Savoy Brand), 31 — Novaspirin, 650—Para-lysol Tablets, 1778—Patent Covered Cooked Ham, 31—Petol Preparations, 434—Prana Sparkcovino, 1778 — Pure Malt Whiskies, 650—Pyrozone Solution, 1778—Sardines (crossed fish brand); Sauerin; Solid Black Mercurial Lotion, 31—Sterilised Milk (green butterfly brand), 1779—Tabloid Phenol Menthol Compound, 1778—Tasteless Cod-Liver Oil, 650—Tawny's Port (Saword's); Tuberculin Tablets (purified), 1778 — Vis Vitæ Bread (V.V.), 434

Anastomosis (arterio-venous) for senile gangrene, 1412; (portal caval), prognostic significance of portal obstruction without external evidence of (Mr. G. H. C. Lumsden), 765
Anatomy, chair of, proposed endowment in Bristol and West of England University, 1658; Clinical, Text-book for Students and Practitioners (Dr. D. N. Eisendrath) (review), 294; Comparative, of Vertebrates (Prof. R. Wiedersheim) (review), 1695; Human, Descriptive (Parts I., II.), (Dr. J. Sobotta) (review), 1017; Essentials of (Dr. J. Sobotta) (review), 1017; Atlas and Text-book of (Dr. J. Sobotta) (review), 1628; in England During Nineteenth Century (Dr. A. Keith), 1; Including Structure and Development, and Practical Considerations (Dr. G. A. Piersol) (review), 164; Pocket, Sixth Edition (Mr. C. H. Fagge) (review), 1217; Practical, Manual and Review of (Prof. D. J. Cunningham) (review), 29; Surgical, Applied (Sir F. Treves) (review), 723; Surgical, Text-book of (Dr. W. F. Campbell) (review), 1697
Anders, Dr. J. M., Text-book of the Practice of Medicine, 1907 (review), 1350
Anderson, Dr. J. F., and Rosenau, Dr. M. J., standardisation of tetanus antitoxin, 1641
Anderson, Sir T. M., obituary, 388, 468
Anderson, Dr. W. D., dosage of new tuberculin, 1513; statistical side of opsonic question, 1106
Andrews, Dr. H. R., and Maxwell, Dr. R. D., difficult labour, 936
Aneurysm, treatment by electrolysis, 1773; aortic, causing compression of vena cava, 1311; saccular, 499; specimen of, 834; sudden death in (Dr. H. A. Smith), 1337; with extensive arterial disease (Dr. S. Taylor), 702; of aortic arch, causing dysphagia, 162; displacement of larynx in, 804; arterio-venous, treated by ligature of common carotid artery, 1484; dissecting, of pulmonary artery, patent ductus arteriosus: rupture into pericardium (Dr. L. Durno and Dr. W. L. Brown), 1693; of thoracic aorta ulcerating into pericardium, 1206; of common femoral artery, 1414; of femoral artery, suppuration from pneumococcal infection, recovery (Mr. H. H. Clutton and Mr. L. S. Dudgeon), 556
Angeioma of right auricle and meatus, 640
"Angina cruris," arteritis obliterans of lower extremity with intermittent claudication (Dr. F. Parkes Weber), 152
Angina accompanied by aortitis, 855; nature of, 1346
Anglo-American Medical Association of Berlin, 907
Aniline, dangers of, 1820
Animals, cruelty to, well-deserved sentence, 1808; diphtheritic affections of, in relationship to those of man (Dr. L. W. Sambon), 1143; humane slaughtering of, 1176; Labyrinth of (Dr. A. A. Gray) (review), 109;
(living) experiments on, 1809;
resuscitating from chloroform
wild, in Madras, 1666
Ankylosis after dislocation of the
hysterical, of lower jaw, 1772
Ankylostomiasis in Australia, 102
Annales Medicales et Bulletin de
de l'Hôpital d'Enfants Hamidié,
view), 1282
Annals of Otology, Rhinology, and
logy (review), 572
Annals of Tropical Medicine and Para
1907 (review), 296
Annandale, Prof. T., obituary, 70;
memorial of, 1035, 1235, 1797;
condolence respecting, passed by
Royal Infirmary Board, 133
Annual Report of the Imperial
of India (review), 795
Anthrax, case of (Parliamentary questi
686, 1043; cases (Dr. J. S. Clarke),
untreated (Dr. J. Cropper), 10
glanders in human beings (Parlia
question), 1043, 1120; in Belfast,
Glamorganshire, 750; in Manchester
459; in Newcastle, 1243; ignorance
1722
Anthropology, researches in, 1806
Antimony (see Chloride of antimony)
Antiseptic surgery, points in history
Lister), 1815
Antitoxic functions, disturbances of,
Antitoxin in successful treatment of
1075; (tetanus), standardisation of,
treatment of "diphtheria of skin,"
years' duration (Dr. A. B. Slater),
Antitoxin of Diphtheria (Bacteri
Diphtheria), edited by Dr. G. F. H.
and Dr. G. S. Graham-Smith (review
Antivaccinators, European, in India,
Antivivisection agitation in New York,
Antrum, maxillary, cystic disease of
Lake), 783; sarcoma of, 163
Antrum, suppuration of, case present
usual features, 854
Anuria, with heart disease, cases, 10
Aorta, regurgitation of, 1213; stenosis
Aorta (abdominal embolism of), 1030;
of (Dr. C. H. Cattle), 1691; (see
also Aortic)
Aortic valve (ruptured), 562, 1079
Aortitis accompanying angina pector
specimen showing form of, associate
sudden death, 1077
Apothecaries' Hall of Ireland,
and Prof. G. H. Darwin, 180
examiners to, 1636; pass-list, 631;
mendations to General Medical
1631
Appeal, charitable, 907
Appel, Dr. L., libellous statements
and medical men, 1555
Appendicostomy, study of (Mr. J. L.
778
Appendicitis, acute: indications for
vantages of early operation in (Mr.
Southam), 491; acute, causing ac
1500; in association with pregnancy
bradycardia in; in children, 467;
1590; deductions from 100 consecutive
tions for, 232; discussion on, 1590;
of, 1154, 1162; first operation
hæmatemesis in, 1225; and
dominal conditions diagnosed by
(Sir W. H. Bennett), 1461; with
peritonitis, cases (Mr. C. A. R.
perforative, during pregnancy, follo
abscess of thyroid gland and abort
H. S. Pendlebury), 1007; in China,
Appendix, abscess of, simulated by
right os innominatum (Dr. B. H.
1770; abscesses of, 430; and cæcum
in strangulated left inguinal
(see also Abscess, appendicular);
during operation (Dr. F. B. B.
Mr. J. D. Malcolm), 1621
Appointments, weekly lists of,
400, 474, 535, 610, 688, 759,
1121, 1187, 1252, 1317, 1383, 1455,
1671, 1732, 1810, 1890
Apprentice, medical, reminiscences
ago, 21
April, 1908, abnormal weather of, 136
Arbroath, outbreak of small-pox in, 1447
Archives of Internal Medicine (review),
Arkle, Mr. A. S., physique and
Liverpool schools, 104
Arm, Tagliacotian skin-grafting of, 104;
pound fracture of, 1843; upper,
injury of, 106; (see also Forearm)
Armies, Hygiene of (Dr. Zavitzianos) (r
504
Armour, Mr. D. J., the Hunterian lect
the surgery of the spinal cord and its
branes, delivered before the Royal Col
Surgeons of England, 633, 765, 838; (

Arms, face, and neck, case of "
limited to, ? cause, 1274

British, health of (Parliamentary
lligence), 826; and the nation, physical
ition of (leading article), 727; health of,
India, 1723; officers, oversight of (Par-
entary Intelligence), 825; (Parliamentary
ion), 936; officers of, lectures in sanita-
for, 127; syphilis in (Maj. H. C. French)
ew), 1421; tuberculosis in (Parliamentary
ical), 936, 1042; (French) disease in,
; territorial (see Territorial army)
Medical Corps, reform in, in Hungary,
order respecting special reserve of
cers, 1357
benzal and cacodylate of sodium in treat-
of corneal ulceration, 1449
nius, S., Immuno-chemistry, 1907
view), 1151
s and Gale lecture on the pathology of
intoxication (Dr. F. A. Bainbridge),
enic in the body, localisation of, 805; in
eatment of syphilis, 630, 1575; risks of,
agriculture, 527
and insanity (leading article), 1219
rial hyperæmia, therapeutic uses of, 1375
ries, disease of, extensive, co-existing with
tic aneurysm (Dr. S. Taylor), 702; Hyper-
of, Sclerosis and Blood Pressure (Dr.
Russell) (review), 431
sclerosis and its causation, 496; caused
alcoholism, 1450; Lancereaux's views
pecting, 1633; nervous manifestations
; in the young, 1025
itis obliterans of lower extremity with
ermittent claudication ("angina cruris")
F. Parkes Weber), 152
y, carotid, common, ligature of, in treat-
t of arterio-venous aneurysm, 1494;
nary, rupture of, causing hæmo-peri-
dium, 443; femoral, aneurysm of, suppura-
from pneumococcal infection, recovery
H. H. Clutton and Mr. L. S. Dudgeon),
(common femoral) aneurysm of, 1414;
monary, dissecting aneurysm of, *patent*
tus arteriosus, rupture into pericardium
L. Durno and Dr. W. L. Brown), 1693;
olism of, treatment, 1514; perforation
by migrating needle, 135; and vein,
oral, excision of, in recurrent sarcoma,
itis with purpura, 1345; rheumatoid,
er, Dr. R., Australia for the sons of pro-
sional men, 1714
er, Mr. W. B., First Aid to Miners (review),
cial respiration, "Silvester method" of,
s and tumours of ovary, 499; treated by
plopexy, 496; paracentesis performed 25
es, 1207

Inebriates, certification of, radical cure, 26; (Dr. T. C. Shaw), 629; Dalrymple Home *for*, 1645; departmental committee *on*, 1292; female, in London (Parliamentary question), 1454; law relating to (leading article), 1426; treatment of, 1451

Infant, acute and transitory dilatation of heart in (Dr. E. Ll. Jones), 1549; binders, dangers and evil *effects* of, 1214; insurance, 1303

Infant life protection, 65, 1042; Act, administration of, 244; Bill, 532; committee, 673; (Emilia Kanthack) (review), 755

Infant Life Protection Bill (No. 2), 1453, 1810

Infant *mortality*, evils of boarding out, 1116; in Bristol, reduction in, 525; in England and Wales, 1357; at Grimsby, 958; in Huddersfield, 443; in Liverpool, 525; in Newport, 1308; schools for mothers (leading article), 114; removal of open safety-pin from œsophagus of, 525; suprarenal hæmorrhage in, 1620

Infants, Diseases of, Manual of (Dr. J. Ruhräh) (review), 165; feeding of, 943

Infants' food in Australia, 466

Infants' Milk Depôt, Leicester, 157

Infanticide, suggested alterations in law and punishment of, 1345; and live birth, 1792

Infection, acute and chronic, of urinary tract due to bacillus coli (Dr. L. S. Dudgeon), 615

Infection, disposal of bodies after, 320

Infectious Diseases Hospital, Melbourne, 1667

Infectious Diseases, Prophylaxis of (Prof. E. Marx) (review), 505; *System of Medicine*, Vol. III. (Prof. W. Osler and Dr T. McCrae) (review), 1014

Infectivity of cancer, 183

Influenza bacillus as cause of fatal endocarditis after eight years? (Dr. F. J. Smith), 1291; at Chatham (Parliamentary question); 686; *diagnostic sign of*, 1032; *the House of Commons* and an open-air hall (A. J. Lawrence), 953; *pericarditis* following (Mr. F. C. Dobie), 1007; and pregnancy, 1397; and ventilation of the House of Commons, 890; (leading article), 652; in Vienna, 465

Infrascapular region, left, abscess of lung in, 292

Ingestion of needles, persistent, and removal by laparotomy (*Dr. A. Nicoll*), 772

Ingleby lectures, dangers and treatment of myoma of uterus (Mr. C. Martin), 1515, 1603, 1682

Inhalation as therapeutic factor, 1445; treatment of consumption and "catarrh," 1236, 1305

Inhaler, improved "ideal," for ethyl chloride and other anæsthetics, 297

Inheritance in its physiological and pathological aspects, 178

Injections, intra-articular, in treatment of *disease* of hip-joint, 620; subcutaneous, of air in treatment of sciatica, 567

Injured. First Aid to, translated by Princess Christian, seventh edition (Dr. F. Esmarch), (review), 1217

Injury or intoxication, doubtful case of ("Drunk or dying"), 122

Inman, Dr. A. C., the effect of exercise on the opsonic index of patients suffering from pulmonary tuberculosis, 220, 232; administration of tuberculin (T R) and other vaccines by the *mouth*, together with (*a*) normal saline solution and (*b*) fresh horse *serum*, 934

Inoculation of bacterial suspensions, 860; *for* plague, 203, 1664; treatment of tuberculosis (Spengler's), 893

Inoculations (specific), 942

Inquest *in Staffordshire* (*Parliamentary* question), 1120

Inquests of coroners upon deaths during surgical anæsthesia, 1304; medical fees at, 441

Insane persons and marriage, 976; patients, upkeep of, 1833

Insane, Third International Congress on Care and Treatment of, date and arrangements, 1502

Insanitary property, evidence of medical *officers of health in questions of*, 1795

Insanitation in Dublin, Recorder's remarks upon, 1257

Insanity, bar to valid marriage, 1711; and art (leading article), 1219; delusions not affecting testamentary capacity, 1855; of emigrants returned to Ireland, 1113; lessons of (leading article), 1851; reception house for recent cases, 596, 675; five years' experience (*Dr. H. C. Marr*), 448

Insects, parasitic, 1518

Inspection of food and meat, practical training in, 1185

Insurance for *medical men*, 1787; of infants, 1303; life, and acute rheumatism, 1851

Intermediate examination for degree of M.B. Lond., 1457

International Drawing Congress, 1185

International First Aid and Life-Saving Congress, 1434

International Society *of* Medical Abstainers, 1727

Interrupter, *new* mercury, for x ray work, 239

Inter-University Conference (Scottish), 679

Intestinal obstruction, acute, 639

Intestine, small, pancreatic diverticula of, 1293; sarcoma of, causing obstruction (Mr. A. C. D. Firth), 851; volvulus of, specimen exhibited, 499; and stomach, living, why do they not digest themselves? 667

Intestines, direct medication of, 1369; *juice of*, comparative influence upon pepsin and pancreatin, 600; obstruction of, 928; acute, 639

Intoxication or injury, doubtful case of ("Drunk or dying"), 122 (see also Acid intoxication)

Intraspinal injection of stovaine, report on 50 cases of analgesia (Mr. L. H. McGavin), 1653

Intrathoracic tumour, 233

Intra-uterine death of fœtus, 1276

Intussusception, with Henoch's purpura, 1215; simulated by Henoch's purpura, 1501; enteric (Dr. F. de H. Hall), 1548; *pathology* and etiology of (Mr. D. C. L. Fitzwilliams), 628, 709

Invalids, travelling facilities for, needed in Italy, 1022

Invention, coincidence in, 630, 1811 (see also New Inventions)

Inventor, maker, and salesman, claims of, 176

Inverness (see Forbes Dispensary)

Inverness district asylum, appointment of medical superintendent, 1724

Inverness Northern Infirmary, admission of cases of pulmonary tuberculosis, 1588

Inverness-shire Sanatorium, 1516

Inversion of uterus, acute, complete, 1078

Iodipin, new syringe for injection of, description, 1253

Iodism and purgatives, 1449

Iola food, 947

Ionian Islands (*Looking Back*), 651

"*Ionic medication*," 248

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND, 532—Cretinism; General paralysis in father, mother, and son; Exhibition of cases, 1345; meeting, 1351

MIDLAND MEDICAL SOCIETY.—Exhibition of cases, 643—Exhibition of cases and specimens, 1083

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—*Hæmatoma of broad ligaments*; Gonorrhœa and uterine sepsis; Cæsarean section for pelvic deformity; Diffuse adenoma; Primary unilateral superficial papilloma of ovary; Supports of pelvic viscera, 22—Woman of future from gynæcologist's point of view, 232—Cystic degeneration of cervix; Cæsarean section; Carcinoma of cervix uteri; Cell dehiscence in pseudomucinous cysts of ovary, 721—Exhibition of specimens; acute complete inversion of uterus; severe concealed accidental hæmorrhage; Primary carcinoma of Fallopian tube, 1073—Analgesia *v.* anæsthesia; Dermoid cyst of mesentery; Pelvic kidney with congenital absence of Müllerian ducts; Exhibition of specimens, 1213—Exhibition of specimens; Cæsarean section; Cornual gestation; Epithelioma of labium majus; Pyelo-nephritis of pregnancy, 1453

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY.—Uterine hæmorrhage as sign of disease, 722

NORTHUMBERLAND AND DURHAM MEDICAL SOCIETY.—*Exhibition of specimens*, 641

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—Anatomy and pathology of eye, 25—Otosclerosis; Alcoholic neuritis; Exhibition of specimens, 163; Exhibition of cases, 292—Complications and dangers of nasal surgery, 293—Exhibition of cases; Difficulties in diagnosis of mediastinal *tumours*, 568—Treatment of tuberculous disease of bone in children, 721—Common causes of urinary obstruction, 791—*Exhibition of cases*, 791, 1079—Diachylon poisoning, 1079—Embolism of the abdominal aorta, 1030—Dangers and evil effects of infant binders; Exhibition of cases, 1214

OPHTHALMOLOGICAL SOCIETY.—Carcinoma of orbit, coloboma of iris in each eye, microphthalmia resembling glioma, optic neuritis in cerebral tumours, exhibition of specimens, 429—Primary facts of colour perception; Exhibition of cases, 563—Optic neuritis in cerebral tumour, 857—Ptosis operations; Tubercle of iris treated by tuberculin; Arterio-venous aneurysm treated by ligature of common carotid artery; *Phlyctenular* keratitis and pustular episcleritis treated by anti-staphylococcic injections; Exhibition of cases and specimens, 1424; Epidemic of contagious conjunctivitis due to pneumococcus; *Hereditary* eye disease; Secondary xerosis; Lower corneal plaques; exhibition of cases and card specimens, 1343, 1344

PATHOLOGICAL SOCIETY OF MANCHESTER.—Exhibition of specimens, 235—Pathology of commonest *gynæcological conditions*; Cancer of body of uterus; Exhibition of specimens, 645—Hæmangeio-endothelioma of liver; Exhibition of specimens, 1214

ROYAL ACADEMY OF MEDICINE IN IRELAND.—Section of Anatomy and Physiology: Iliac colon in relation to hernia; Exhibition of specimens, 566—*Colour* fatigue; Fissure of Rolando, 1437—Section of Medicine: Diphtheritic fever; Eye strain, 23—Nephritis, 566—Duodenal ulcer, 1212—Section of Obstetrics: Exhibition of specimens; Teaching of obstetrics, 105—Exhibition of specimens; Puerperal infection, 720—Exhibition of specimens, &c.; Tuberculous *salpingitis*, 1077—Abnormal placenta; Operative treatment of puerperal infection, 1273—Exhibition of specimens; Obstetrical report of the Rotunda Hospital for 1907-08; Gynæcological report of the Rotunda Hospital for 1906-07, 1774—Section of Pathology: Exhibition of specimens, 233, 789, 1077—Exhibition of specimens; Spinal abnormality; Pathological report of Rotunda Hospital, 1554—Section of State Medicine: Alcohol and mental disease, 792—Registration of diseases in hospitals; Vital *statistics of aged*, 1553—*Section of* Surgery: Grafting of fibula to tibia; Post-anæsthetic vomiting, 291—Exophthalmic goitre, 292—Gall-stones; Exophthalmic goitre, 861—Tuberculosis *treated by* tuberculin; ureteral calculus, 1152

ROYAL SOCIETY OF MEDICINE.—General meeting, 732—*Clinical Section:* Status lymphaticus; Exhibition of cases, 190, 551—Hermaphroditism in which uterus occupied sac of inguinal hernia; Angina pectoris with aortitis; Cerebellar tumour with proptosis; Purpura hæmorrhagica with fatal result from cerebral hæmorrhage, 855—Fatal lymphocythæmia in early life; Multiple rheumatic nodules in adult; Right hemiplegia with optic atrophy; Exhibition of cases, 1206; Arterio-venous anastomosis for senile gangrene; A case of leucoderma; Death with symptoms of Addison's disease; rupture of brachial plexus, 1412—Exhibition of cases, 1413—*Dermatological Section:* Exhibition of cases, 101, 425, 718, 1008—*Laryngological Section:* Exhibition *of cases and specimens*, 161, 553, 857, 1076, 1344—*Medical Section:* Kinematograph in medicine; pathology and treatment of chronic constipation, 427—Acute suffocative catarrh; Acute ulcerative colitis with unusual symptoms, 717—Administration of *tuberculin and other* vaccines *by the* mouth, together with (*a*) normal saline solution and (*b*) *fresh horse* serum, 1623—*Obstetrical and Gynæcological Section:* Supports of *pelvic viscera*, 100, 1770—Exhibition of specimens, 100, 101—Enucleation of uterine fibro-myoma during seventh month of pregnancy; Hæmorrhage into pons varolii as immediate cause of death in eclampsia of pregnancy; Exhibition of specimens, 231, 232—Ovarian dermoid with secondary cysts connected with omentum; Exhibition of specimens, 638—Tuberculosis of Fallopian tube; Cæsarean hysterectomy; Excretion of creatinin, 1275—Intra-uterine death of fœtus, 1276. *Odontological Section:* Organisation of research, 178—Exhibition of specimens; Treatment of suppurative periodontitis in displaced teeth; *Treatment of children from* dental point of view, 1002—Exhibition of specimens; Movements of the mandible, 1344—Extraction of an upper wisdom tooth; Pyorrhœa alveolaris; *Heredity* and dental disease, 1624—*Otological Section:* Ménière's disease; Primary *epithelioma (?)* of tympanum; Exhibition of cases and specimens, 496—Exhibition of cases and specimens, 787—Clinical pathology of aural discharges; Exhibition of cases and specimens, 1416. Pathological Section: Diffuse cancellous osteoma of femur, 288—Tuberculous endocarditis; Effects of calculi upon photographic plates in dark; Malignant disease of rectum; Chimney-sweep carcinoma, 289—Acidosis in pregnancy, 637—Bang's method of glucose estimation; Œsophagostoma inflatum; Parasites of malaria, 786. *Surgical Section:* Subphrenic abscess, 159—Coxa valga, 560—Lumbar puncture in treatment of otitic meningitis, 654—Treatment of ulcerative proctitis by zinc cataphoresis; Sciatica and surgical treatment, 1452—Reduction of old subcoracoid dislocation of humerus by excavating glenoid cavity through posterior intermuscular incision; Cystic tumour of suprarenal body successfully removed by operation; Compound fracture of arm; Ununited fracture treated by planting small fragments of bone between the ends, 1841, 1842, 1843 *Therapeutical and Pharmacological Section: Action of digitalis* in cardiac disease; Reminiscences of an apprentice 50 years ago, 27—Nutmeg poisoning; Arteriosclerosis and causation, 495—Therapeutics of diet, 718—Hypnotism, 1076—*Rheumatism* and chorea in children, 1415

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—Exhibition of cases, 24—Acute rheumatism, evidence in support of bacterial origin, 1014—Exhibition of cases, 1213—Difficulties of diagnosis; Uterus *bicornis bicollis*; Carcinoma of cæcum and colon, 1346

SOCIETY OF ANÆSTHETISTS.—Status lymphaticus and general anæsthesia, 564

SOCIETY FOR THE STUDY OF DISEASE IN CHILDREN.—Congenital hypertrophic stenosis of pylorus; Exhibition of cases, 497—Acute intestinal obstruction, 639—Exhibition of cases and specimens, 640—Granular kidney; Exhibition of cases, 1013—Henoch's purpura with intussusception; Tetanus neonatorum; Exhibition of cases, 1213—Exhibition of cases and specimens; Empty bronchus treatment by posture in bronchiectasis, 1433

SOCIETY OF TROPICAL MEDICINE AND HYGIENE.—Ankylostomiasis in Australia; *Physaloptera mordens*, new parasite of man; Part played by metazoon parasites in tropical pathology, 102—Biographical sketch of Prof. F. Schaudinn, 235—Unequal distribution of filariasis in the tropics, 292—Kala-azar; Exhibition of slides, 719—Dysenteric diarrhœa in the tropics, 1210—Rôle of filaria in production of disease; Use of quinine during pregnancy, labour, and puerperium, 1552

SOUTH-WEST LONDON MEDICAL SOCIETY.—Treatment of pneumonia and complications, 25—Diagnosis and treatment of hæmorrhage from mouth, nose, and stomach, 234—Practical applications of *electricity* and x rays, 645

UNITED SERVICES MEDICAL SOCIETY.—Cause, prevention, and treatment of Mediterranean or undulant fever, 21—Hernia, recurrent, operation for, 161—Physiological principles of physical training; Hospital ships, 858—Effects of heat in the tropics, 1483—Exhibition of cases, 1078—Probable diseases of territorial army, 1277—Plea for more detailed study of soldier's heart, 1845

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—Exhibition of specimens, 792—Examination of pelvis and abdomen during pregnancy; Some neglected remedies, 1417—Causes of unconsciousness, 1845

WIGAN MEDICAL SOCIETY.—Exhibition of cases; Renal calculi, diagnosis and treatment, 1279

WINDSOR AND DISTRICT MEDICAL SOCIETY.—Treatment of puerperal eclampsia, 107—Exhibition of cases, 731—Danger of delay in performing operations, 792—Exhibition of cases; Pre-operative treatment of non-malignant disease of stomach, 1279

Medical students of London, needs of, 52, 130, 1318, 1797
Medical studies, coördination of (leading article), 33
Medical trial, 1182
Medical women, education of, 1112; in Edinburgh, 1034; modern, pioneer of, and her predecessors of the Middle Ages, 173; Post Office and medical attendance (Parliamentary question), 1525
Medication, direct, of intestines, 1369
Medicine and diplomacy, 1785

MEDICINE AND THE LAW.—Apology for unjustifiable advertisement, 1506—Assaults on officials discharging their duties, 1651—Authority of manager to obtain medical assistance for workmen, 1791—Brown *v.* Butler, negligence in *supplying* impure water, 1099—Burning and overlying of children, 123—Canine specialist, 1167—Casual employment under the Workmen's Compensation Act, 1711—Christian Science treatment, 163—Cocaine poisoning case, 809—Cruelty to children, medical evidence, 163—Damages £500 for libelling a medical practitioner, 517—Death from eating chromate of potassium, 1298—Death from heat on board ship held to be an accident, 123—Delusions not affecting testamentary capacity, 1665—Disposal of infected *bodies*, 300—Evidence as to ability to work, 1855—Exemplary sentence on milk dealer, 1298—Fergusson *v.* the Malvern urban district council, 517—Health and safety of young children, 448—Herbalist sued unsuccessfully by *Society of Apothecaries*, 1162—Hypnotism as an excuse for crime, 1651—Infanticide and live birth, 1792—Insanity a bar to valid marriage, 1651—Jamaica rum and Demerara rum, 1298—Kissing the Book, 447—*Legal* liability of anæsthetist, 1167—London parks as sleeping places, 1711—Lunacy Act, 1890. offence under, 808—Malt vinegar, 123—Medical attendance on servants, is a master liable? 447—Medical attendance on workmen, 1791—Medical certificates for school children, 517—Medical fees, an important decision, 1365—Medical man and coroner, 1231—Medical man's motor-car in collision, 1298—Motor grease in streets, 1507, 1651—Notification of Births Act (1907), 731—Overlaying and Children's Bill, 1507—Pistol again, 1100—Plowden, Mr., and evidence of divisional surgeons of police, 962—Prescribing druggist and death from opium poisoning, 1028—Professional secrecy, 669—Problem of expert *testimony*, 1651—Prosecution under Cremation Act, 1507—Prosecutions for sending indecent matter by post, 962—Protection of infant life, 1507—"Separate existence" of newly born child, 1365—Troutbeck, Mr., on deaths *under anæs*thetics, 1298—Tucker *v.* Wakley and Another, 301—Vinegar, what is it? 808—Voice production, 588

Medicine, Clinical, Chair of, at Glasgow University, 1832
Medicine, development of, in Russia, 1565
Medicine, lay, 829
Medicine, Minor, Treatise on Common Ailments (Dr. W. E. Wynter) (review), 866

Obstetric aid to poor in Florence, 1038
Obstetrical *report of Master of Rotunda Hospital*, 1774
Obstetrics, teaching of, changes in, suggested by General Medical Council, 106; Text-book for Use of Students and Practitioners (Prof. J. W. Williams) (review), 645; and gynæcology, analgesia v. anæsthesia in (Sir W. J. Sinclair), 1541
O'Carroll, Dr. J. P., duodenal ulcer, 1212
Ocular fatigue, treatment of, 897
Œdema, chronic inflammatory of submucous tissue of nose, 1773; of hands and feet with mediastinal affection, 1208; limited to arms, face, and neck, ? cause, 1274; lymphatic, relief by lymphangioplasty (Mr. W. S. Handley), 783; pulmonary, acute, 48, 123, 261, 262, 575; (Dr. J. M. Pearson), 427; (Mr. W. B. Silas), 288
Œsophagostoma inflatum, 757
Œsophagus, foreign body in, 1114; idiopathic enlargement of, 758; of infant, removal of open safety-pin from, 523; open safety-pin in, of child aged five months (Mr. J. S. Manson), 20; perforation of, specimen, 1077; by a rabbit bone, septic inflammation, &c., death (Mr. R. Lawford Knaggs), 933; removal of foreign body from, 897; removal of open safety-pin from, in child, aged five months, 283
O'Farrell, Dr., discussion on operative treatment of puerperal fever, 1279
Officers, cabins for, allocation on board ship, 1654
Official Directory of Nurses Bill, 1119, 1331
Official illnesses, 576
Offord, Mr. J., Græco-Roman Branch of the Egypt Exploration Fund, 1655
Ogilvie, Dr. G., speech at banquet of French Hospital, 1523
Oil, grey, properties of, 177; stomatitis due to, 1247
Oil of sage, fatal case from overdose of, taken as "cure" for asthma (Dr. H. T. M. Whitling), 1074
Ointment bases, 877
Old Epsomian Club triennial dinner, 1799
Oldham, overcrowding in, 1670; public vaccination in, 119
Oliver, Dr. G., pathology and balneotherapy of rheumatism, 1551
Oliver, Dr. J., hypertrophy of the urinary bladder in a woman with an ovarian cyst, 1151
Oliver, Dr. T., case of dissecting aneurysm of the thoracic aorta ulcerating into the pericardium, 1206
Oliver, Deputy Surg.-Gen., W.S., obituary, 1367
Oliver-Sharpey Lectures on present condition of our knowledge regarding the functions of the suprarenal capsules (Prof. A. E. Schäfer), 1531, 1676
Omentum in connexion with ovarian dermoid with secondary cysts, 635
Omnibuses (see Motor omnibuses)
Ontario, Conference on Tuberculosis in, 972; feeble-minded in, 1664; hospitals and charities, 975; small-pox epidemic in, expense of, 289
Openshaw, Mr. T. H., multiple dislocation in child two weeks old, 563; appliance for obtaining extension of spine in treatment of scoliosis and caries, 1205
Open space for East London, 1023

"Open spaces" movement in Birmingham, some results of, 1091
Operating theatres, new, at Royal Free Hospital, 181
Operations, dangers of delay in performing, 792; feigned, protest against, 1804; necessity of obtaining patient's consent for, 1642; surgical, age in relation to prospect of recovery after, 1518; performance of 61, in one day, 121
Ophthalmia, Manual of Operations for (Mr. F. P. Maynard (review), 1216
Ophthalmia neonatorum, 859; experiment in treatment (Dr. A. A. Mussen and Dr. A. N. Walker), 1257; *(Parliamentary question)*, 904
Ophthalmic surgeons, congress at Oxford, date, 1809, 1883
Ophthalmitis (sympathetic), 1079
Ophthalmology, Congress of, Eleventh International, programme, 472; international prize for, 915; (review), 1423; at Oxford, 803; solecisms of terminology in, 1870; Text-book of (Dr. E. Fuchs) (review), 1156
Ophthalmo-tuberculin reaction (Calmette's), 397, 439, 643; *cases with*, 291; followed by prolonged conjunctivitis, 1163; in diagnosis of tubercle, warning against indiscriminate use of (Mr. A. M. Ramsay), 716; notes from 40 cases, 640; in tuberculosis, 681
Opie, Dr. E. A., acute delirious mania and acute mania, 1385
Opium, safeguarding cultivation as specific against fever in India (Parliamentary question), 1013; poisoning, death from, following incautious prescribing by druggist, 1029; question, feeling with regard to, in Shanghai, 1115; smoking in China, stamping out of, 1667; in China, 529; traffic, 1451
Opium habit, 821
Oppenheimer, Dr. H., medico-legal significance of gonorrhœa, 1555
Opsonic index, accuracy of estimations of (Mr. L. Noon and Mr. A. Fleming), 1203; effect of exercise on, of patients suffering from pulmonary tuberculosis (Dr. A. C. *Inman*), 220; of nature, sidelights on, 186; (see also Tuberculo-opsonic index)
Opsonic Method of Treatment (Dr. R. W. Allen) (review), 648; question, statistical side of, 1106
Opsonins, observations on, with special regard to lupus vulgaris (A. Reyn and R. Kjer-Petersen), 919, 1000
Optic atrophy, with myxœdema, 1203
Optic nerve (see Nerve, optic)
Optic neuritis and inducement of premature labour, 1726
Optician, prescribing, 829
Opticians, certification of, 1356
Oral Cavity and Nose, Naso-pharynx and Larynx, Diseases of (Dr. A. Brück) (review), 1776
Orbit, carcinoma of, 429
Organ-grinders, children as stock-in-trade of, 952
Ormerod, Dr. J. A., pityriasis rubra, 428
Orthodontia, treatment of (Mr. H. C. Highton), 1836
Orthopædics, Surgery of (Dr. A. Thorndike) (review), 1283
Os innominatum, right sarcoma of, simulating appendix abscess (Dr. E. H. R. Harries), 1770
Osborne, Isle of Wight (see Convalescent home)
Oscillatory current cautery, 1176
Osler, *Prof.* W., erythræmia (polycythæmia with cyanosis, maladie de Vaquez), 143; *La Pratique de la Médecine*, 1908 (review), 295; and McCrae, Dr. J., System of Medicine, by Eminent Authorities in *Great Britain*, the *United* States, *and* the Continent, vol. iii., Infectious Diseases, Diseases of the Respiratory Tract, 1908 (review), 1014
Osseous Formations in and about Muscles *due to* Injury (Mr. R. Jones and Dr. D. Morgan) (review), 295
"Ostanxin," new antirachitic drug, 1727
Osteo-arthritis of elbow in old *fracture* of humerus, skiagrams of, 561; of knee in dislocation of patella, 561
Osteo-fibroma of maxilla (Dr. A. Wylie), 1343
Osteology, Pocket (Mr. P. Turner) (review), 1422
Osteoma, diffuse cancellous, of femur, 288, 498
Osteomalacia, 1418; treatment by adrenalin, 1183
Ostertag, Dr. R., Handbook of Meat Inspection, 1907 (review), 1081
O'Sullivan, Prof., aortitis associated with sudden death, specimen showing *form of*, 1077
Otitis media, chronic suppurative, followed by epithelioma (?) of tympanum, 496; complicated by cerebro-spinal meningitis, 160; pneumococcal, 942; *purulent*, in secondary syphilis, 787; purulent, chronic, involving sigmoid sinus, 162
Otology, Text-book of, for Physicians and *Students (Dr. F. Bezold and Prof. F.* Siebenmann) (review), 1215
Oto-rhino-laryngological Technique, Semeiotics and Therapeutics, for use of Student and Practitioner (Dr. E. Escat) (review), 1775
Otosclerosis, 163; (Dr. A. Denker) (review), 1015
Ovaries, malignant disease of, 1418
Ovary, bilateral dermoid ovarian cysts complicating pregnancy, 721; cyst of, hypertrophy of urinary bladder in woman with,
Overcrowding, in Oldham (Parliamentary question), 1670; in Scotland (Parliamentary 1151; cyst of, specimen of ectopic gestation with, 1774; ruptured, 721; cysts of, pseudo-mucinous, cell dehiscence in, 721; dermoid of, with secondary cysts connected with omentum, 638; fibroma of, 1488; primary unilateral superficial papilloma of, 23; teratoma of (Mr. S. G. Shattock), 479; tumour of, and ascites, 499; tumours of, specimens, 163
question), 608, 1121
Overlying of children, 123, 749
Overlying, and Children's Bill, 1507
Ovum from horn of bicornuate uterus, 720
Owen, Dr. A. L. (the late), *memorial to*, 1119
Owen, Sir Isambard, re-elected senior deputy chancellor of University of Wales, 1523
Oxford, ophthalmology at, 803; three decades of scientific work in (1650–1680) (leading article), 1020; University of, 606, 1380, 1523; Congress of Ophthalmic Surgeons, date, 1809, 1888; graduation, 472; medical news, 1659; pass-lists, 137, 1313; *Radcliffe travelling* fellowship 1908, 239
Oxygen, inflation of bladder with, 22; mechanical separation of, from air, 1783
Oysters, sale of, 1884
Ozone in successful treatment of cavity of lung (Mr. G. Stoker), 1148

P

Pacific coast, plague on, 63
Pageant (Jubilee) in Vienna, ambulance at, 1857
Paget, Mr. S., Research Defence Society, 1440
Paintings of Daltonians (colour-blind), 873
Palate, deformities of, relation of adenoids to, 443
Palmer, Dr. F. S., progressive muscular atrophy, 1209
Palsies, re-education of muscles in, treatment of, 1661
Paman, Henry, Gresham Professor 1679–1689, work of, 1193
Panama, three years medical and sanitary record in (Mr. J. G. Leigh), 1646
*Pan-Anglican thankoffering (see Thank*offering)
Pancreas, disease of, treated with pancreatin, 1450
Pancreatic diverticula of small intestine, 1293
Pancreatin in treatment of pancreatic disease, 1450; and pepsin, comparative influence of intestinal juice upon, 600
Pancreatitis with jaundice (Dr. C. Watson), 967; and acute parotitis in scarlet fever (Dr. S. P. Phillips), 853; chronic, two cases exhibited, 232
Pannus, gonorrhœal inoculation of eyes affected with, 200
Papilla, renal, persistent hæmaturia from varicose veins of, 1856
Papilloma of larynx, 25; primary unilateral superficial, of ovary, 23; of trachea, case of, 578
Paracentesis performed 25 times in ascites, 1207
Parodi, Dr. F., treatment of uterine *gonorrhœa*, 399
Paraffin, bone cavities treated by stopping with (Dr. A. J. Walton), 155; injection for depressed nose, 1210; in Surgery (Dr. *W. H. Luckett* and Dr. F. T. Horn) (review), 1282
Paralysis abducens, crossed, 787; ascending, acute (Mr. C. W. Vining), 425; *ascending*, fatal, following anti-rabic treatment, 1884; associated, of bladder accompanying functional paraplegia, case of (Dr. Æ. Rose), 1411; general, in father, mother, and son, 1345; *of superior* oblique muscle of eye as result of direct injury, 1708; (see also Brown-Séquard's paralysis)
Para-lysol tablets, 1778
Paramore, Dr. R. D., discussion on supports of pelvic viscera, 101; the supports-in-chief of the female pelvic viscera, 1760, 1770
Paraplegia due *to* intra-medullary lesion; *treatment by removal* of local accumulation of fluid (Dr. W. B. Warrington and Mr. K. W. Monsarrat), 94; functional, with associated paralysis of bladder, case of (Dr. Æ. Rose), 1411; with sarcoma of spinal meninges, 105
Parasite, intestinal, affecting man in *Uganda* (Physaloptera mordens), 102
Parasites, metazoon, and tropical pathology, 102; (see Insects, parasitic)
Parathyroid glands, 811; function of, 659; pathology of, 1566
Paresis a germ disease, 1723; of external rectus in right eye and enophthalmos with loss of lateral movements in left eye, 643

PARIS, CORRESPONDENCE FROM.—Dermotherapy; Hygiene of barracks and epidemics therein; Pulmonary tuberculosis, treatment by sea-water; Strike of medical men, 199—Revolver bullet apparently lodged in apex of heart; Semi-resection of elbow for irreducible dislocation *of both bones of forearm*, 200—School for nurses at the Salpêtrière; Extension of the Hospital for Charity Children; Hæmarthrosis of the knee; Resection of the lower jaw, with immediate mechanical re*placement thereof*; *Effect of nervous stimulants* on the capacity for work; A "rest-house" for the French medical profession, 267—Treatment of Hebra's prurigo by fresh liver bouillon; Ophthalmic reaction of tuberculin; *Anti-diphtheritic serum in affections* of the eye; Nomination of a professor, 391—Purification of sewage; Absorption of the upper jaw in a case of syphilitic tabes; Strike of medical men, 393—Cholera statistics; Diphtheria statistics; Disinfection of uniforms; Medical evidence, expert, and criminal law in France; Milk, poisonous from cows fed on beet; *Sleeping* sickness in a white man, 463—Risks of arsenic in agriculture; Immediate operation in gun-shot wounds of the auditory region; Treatment of old-standing injuries of the *wrist by total resection of the carpus*, 527—Comparative influence of intestinal juice upon pepsin and pancreatin; Meal (farine) of Netté; *Hygiene of dwellings*; Treatment of diseases of the hip-joint by intra-articular *injections*, 600—Thyroid treatment of chronic rheumatism; Poison of Koch's bacillus tuberculosis; Arsenic in the treatment of syphilis, 630—*Obituary*, 601—Medical "entente cordiale"; Ophthalmo-reaction in tuberculosis; New chair at *the* Faculty of Medicine; Basal pulmonary abscess, 631—Absorption of tuberculin by the rectum; *Method of resuscitating* animals from chloroform syncope; Vacant chairs in the college of France; State control of the medical staffs of provincial hospitals, 752—Disinfection of books; Chair of *hydrology at Paris*, 753—Individual isolation of patients in children's hospitals; Exophthalmic goitre, treatment; Implantation of metal plate after fracture of skull, 817—Surgery of liver; Riot at Clermont-Ferrand School of Medicine; "Roux hygienic pipe," 818—Transmission of enteric fever and cholera; Treatment of ocular fatigue; Professional scandal; Removal of a foreign body *from* the œsophagus; Treatment of sciatica and rheumatism; Therapeutic use of cholesterine, 897—An accident and its sequel; Military hygiene and epidemiology; Adulteration of drugs; Roland *Bonaparte* benefactions for scientific research; Congress of Climato-therapy and Urban Hygiene, 971—Action of radium on the blood; *Ambulance drawn by* a dog; Quinine in Algeria; Treatment of hæmarthrosis; Jubilee of Dr. Magnan, 1037—Dislocation of the carpus; Statistics as to students; Therapeutics of colloidal silver; scarlet *fever*, 1113—*Consumption of tobacco*, 1114—Municipal grants in aid; medical trial, 1182—Academy of Medicine; Hospital drama; Obituary; Stomatitis due to grey oil; Workmen's *Compensation* Act, 1247—Fat treatment of diabetes; Clinical employment of ethyl chloride as a general anæsthetic; Action of bicarbonate of sodium on *gastric secretion*; *Disease in the army*, 1310—*Principal* causes of mortality from diphtheria since the introduction of serum therapy; Sugar refining as a dangerous occupation; Therapeutic uses of venous and arterial hyperæmia; Post-graduate medical teaching; Obituary: M. Chamberland, 1376—Relapsing fever in Tonkin, 1448—*Cacodylate of sodium and arrhenal in treatment of* corneal ulceration; *Reforms* in medical education; Iodism and purgatives, 1449—Spinal anæsthesia; *Foreign bodies* in the auditory canal; *Determination* of live or still birth; Bicarbonate of soda in gastric affections; Methylene blue in treatment of malaria, 1517—*Remarkable* medical evidence in the case of an alleged murderess; Chronic appendicitis; Exhibition of ambulance dogs, 1589, 1590—Administration of antidysenteric vaccine by the mouth—Syphilis and myopia; Re-education of the muscles in the treatment of different palsies; Thermic effects of high-frequency currents on the body; Tuberculous rheumatism; Diagnosis of cancer by a specific reaction with micrococcus neoformans, 1661—Treatment of whooping-cough by the milk of animals infected with anti-tetanic serum; Arterio-sclerosis; Consumption of alcohol in France; Treatment of constipation by electricity; Protest against feigned operations; Iodide of potassium in the treatment of leprosy, 1804—French Society for Study of Cancer; Sale of oysters; Fatal ascending paralysis following on anti-rabic treatment; French Society of Hygiene and the fishermen, 1884—Home of rest for the aged; Pathemimia; Curious observation upon birds, 1885

Paris Faculty of Medicine, Sir D. Duckworth's lecture, 443; *hospitals of, nursing in* (leading article), 1555; medical education in, 514; medical men of, in sixteenth century, 1094; "sweating system" in, 655
Parish medical officers, Scottish, question of, 1515
Park *Hill* Civic Hospital, closing of, 1243
Parker, Mr. A. P., appointment, 1523
Parker, Mr. Rushton, ununited fractures treated by bone-grafting, 104; compound *fracture of arm*, 1543
Parkes, Dr. L. C., and Kenwood, Dr. H. R., Hygiene and Public Health, 1907 (review), 1491
Parkinson, Dr. J. P., synovitis of knee-joint exhibited, 498; fibrosis of the lung with bronchiectasis, 854; tuberculosis of kidney with pyonephrosis, 1023; aortic regurgitation, 1213; tetanus neonatorum, 1213; on rectal administration of antitoxic sera, 1273; and Hosford, Mr. J. S., cerebellar tumour with proptosis, 856
Parks (see London parks)

PARLIAMENTARY INTELLIGENCE.—*Current Topics*: Opening of Parliament; Pharmacy Ireland Acts; New Bill; Legislation on milk-supply; Alcohol and tuberculosis in Ireland, 473—*House of Lords* (Jan. 29th): International conference on sleeping sickness; An Address

ON

HUMAN ANATOMY IN ENGLAND DURING THE NINETEENTH CENTURY.

Delivered to the Students of the London Hospital

By ARTHUR KEITH, M.D. ABERD.,
F.R.C.S. ENG.,

LECTURER ON ANATOMY AT THE LONDON HOSPITAL MEDICAL COLLEGE.

GENTLEMEN,—In the opinion of the great majority of medical men the subject of human anatomy, so far as it can serve the purposes of the physician and surgeon, has become in our time as perfect as the skill of man can make it. I will not venture to say that such an opinion is unreasonable. The human body is a comparatively small and strictly circumscribed field wherein generation after generation of anatomists have laboured during many centuries, treasuring and perpetuating their observations in an almost endless series of tomes. If finality be possible we ought now to have reached it. One who believes that the stage of perfection has been reached might cite our modern text-books of anatomy as evidence; they seem to leave nothing further to be desired; their bulk ought to betoken finality. Never before has the structure of the body been displayed so exhaustively, so accurately, or so temptingly as to the young man who commences the study of medicine to-day. But unfortunately the condition of a subject, its perfection or imperfection, cannot be measured by an examination of its text-books. As regards human anatomy it can be judged only by seeing how well it serves the needs of medical men, and when modern anatomy is measured by this standard it seems to me to fall very far short of perfection.

To make my meaning clear, let me cite a number of structures on which anatomists, physicians, and especially surgeons have concentrated their most strenuous endeavours during the last two or three decades. I will select the appendix vermiformis as my first instance. Its size, shape, position, variations, and development are described in the most elaborate detail, but nowhere can one find answers to these questions: Why is its lumen so small, its muscular coat so thick, and its supply of lymphoid tissue so abundant? Why does it, like the thymus, tonsil, Peyer's patches, and lymphoid structures generally tend to undergo an atrophy with age? Yet the answers to these questions seem to me to constitute the very essence of the anatomy of the appendix. Could the anatomist answer these, then indeed we should know something of its nature. To call the appendix a "vestigial structure" or a "cæcal tonsil" is merely a manner of covering our ignorance of its nature by a gloss of knowledge—a very remarkable thing in the case of a structure that causes the death of thousands of persons. The great intestine will serve as another instance. It has been most minutely described and demarcated into segments; its fixation, its tæniæ, its form, and course are set forth in our text-books at great length. But no one asks why it is so placed and fixed, why its outer muscular coat is grouped in tæniæ, or why it takes such a remarkable and tortuous course. Certainly the theory of its being a useless structure and a cesspool, promulgated by Metchnikoff and accepted by so many, will not assist us in explaining the significance of these features. Many other structures might be cited, such as the gall-bladder, the prostate, the epididymis, the antrum of the mastoid, the nasal air sinuses, the semilunar cartilages of the knee, the erector spinæ, or the folds and arrangement of the peritoneum. On each one of these structures anatomists and surgeons have focussed their attention of late years with the result that we have accumulated an enormous catalogue of their physical characters, but of their nature, meaning, or function little or nothing. That a generation of medical men in seeking to establish a scientific basis on which to apply treatment should rest content with merely describing the physical characters of parts which are so often the seat of disease seems to me a very remarkable defect in our modern methods of anatomical inquiry. This grave defect I believe to be a direct result of the modern conception of human anatomy.

What is our modern conception of human anatomy? If you turn to examination papers you will find it; most of the questions begin with the word "describe." Turn to our text-books and you will find that such and such a part "presents for description or examination the following features" as if the main reason for the very existence of the part was for "the purposes of description." Our anatomical text-books are what they claim to be—works on "descriptive" anatomy. The art of description has become the chief purpose of anatomy. We describe to you the heart in its utmost details—its shape, surfaces, borders, and grooves; we treat it as a still-life study, a thing of crests and angles so utterly unlike the palpitating organ you afterwards have to place your stethoscope over that you cannot imagine the anatomical and clinical heart to be the same thing. In my student days two books on anatomy were held up for particular commendation; one was Ward's "Osteology," the other Ellis's "Anatomy" (now in my opinion much improved). Both are magnificent examples of accurate and painstaking observation and description. If anatomy be but the correct description of parts, then, indeed, our subject has reached a finality. To my mind the apparent futility and barrenness which characterise so much of our modern anatomical work are due to the fact that this *descriptive* ideal has been accepted and that the business of the anatomist is to describe appearances, not to explain them.

The remarkable story of how anatomy came to be regarded in England as a "descriptive science" commences towards the close of the eighteenth century. In the latter part of that century British anatomists were, as indeed they had always been, much more than mere describers. John Hunter in London and Alexander Monro (secundus) in Edinburgh had modelled themselves on the prototype of English anatomists, William Harvey. In no sense was Harvey a descriptive anatomist: he studied the human body to understand the significance, not the form of the various parts. He perceived that the hypotheses of his time did not account for the structure of the heart nor for the arrangement of its blood-vessels. It was to explain these that he postulated the theory of the circulation of the blood, the truth of which he afterwards proved by experiment. It was in the same spirit that Hunter, Monro, and the two Bells pursued the study of anatomy in England in the later decades of the eighteenth century. To Hunter the observation of a fact was but the prelude to an attempt to explain its significance. It was not enough to record that the wall of the aorta was twice as thick as that of the pulmonary artery or that the walls of some veins were thick and of others thin: he immediately set to work to find out the significance of these facts; he appealed to comparative anatomy, to embryology, to pathology, and experiment for an explanation. Monro formed a true conception of the manner in which the cerebral circulation was carried on from a consideration of the anatomy of the parts; he did not rest content with merely describing the venous sinuses within the skull but sought for the reason why the larger intracranial veins assume such a peculiar form. In the "System of Dissections" by Charles Bell,[1] and in the text-book first issued in 1793 by John and Charles Bell, one sees the same spirit at work. Thus, up to the end of the eighteenth century there was a strong school of British anatomists who regarded dissecting as a means for obtaining not a description but an understanding of the human body. By the end of the second decade of the nineteenth century this robust British school had almost ceased to exist, its extinction being due to the introduction of a French fashion. At that time our young men turned to Paris for their medical ideals, just as now our young women seek there the standard of fashion. Our young anatomists preferred the clear, methodical descriptive manner of the Parisian school to the heavier methods of their predecessors. Descriptive anatomy had thriven amazingly in the French schools. It was the creation, I think, of the famous Winslow, professor of anatomy, physic, and surgery in the University of Paris, in the middle decades of the eighteenth century. He had (but to a very high degree) that gift which many of his countrymen still retain of engaging the rapt attention of his readers and hearers by the sheer lucidity and orderliness of his descriptions. While merely conveying to his hearers or readers what they might see with their own eyes at a glance he left with them the pleasant impression that they were drinking at the very fountain-head of pure knowledge. This special gift of vivid description has often

END OF THE FIRST VOLUME FOR 1908.

PRINTED and PUBLISHED by the REGISTERED PROPRIETORS at No. 423, Strand, and Nos. 1 and 2, Bedford-street, Strand, in the Parish of St. Martin-in-the-Fields, Westminster, in the County of London.—Saturday, July 4th, 1908.

ere infers that neither orifice can be closed; that they are ways open, in systole and diastole; and that regurgitation blood during the contraction of the auricle is prevented r the pressure in the veins being normally greater than e diastolic pressure in the right ventricle. I am now nvinced that, as far as concerns the inferior caval orifice, hn Bell's conception is true, and I am not so certain I was that the band of muscle above mentioned—the nia terminalis—is absolutely sufficient to occlude the per orifice in man, although there can be no doubt from s arrangement that it does diminish it in auricular systole. ithin the right auricle, too, turning again to modern xt-books, the student is expected to examine the tubercle Lower which is believed to direct the current of blood owing in from the inferior vena cava—a miniature breakater. Bichat expresses a doubt as to the tubercle; he eaks of it as the "tubercle which Lower saw or believed e saw." Bell expresses a more definite doubt. "It is mmonly absent," he states, and adds "if it were not really n imagination of that celebrated anatomist." Now, what ower represents in the figure showing this "tubercle" is e heart of the calf or sheep, in which the upper and lower enæ cavæ enter the right auricle close together and set at a irly acute angle to each other, so that the band of muscle etween their orifices is very apparent on the interior of the uricle. It was to this intercaval band of muscle which ower gave the name of tubercle, a term inappropriate in he sheep's heart and altogether inapplicable to the human eart.

Many further instances might be cited to show how far the doption of the descriptive method has obscured our real bject in studying the anatomy of the heart. I will refer to nly one—namely, the structures concerned in tricuspid regurgitation All of us who now teach human anatomy must ave been familiar as students with the clinical doctrine that nder certain conditions the tricuspid valve became incompetent. Yet, in our published descriptions we never ask the tudent to look beyond the cusps of the valve and the fibrous ing—a very delicate ring it is—which *surrounds* the orifice s the means of securing competency. The relationship of he musculature at the base of the right ventricle to this rifice and the effect of its contraction on the size of the rifice were scarcely mentioned, yet from a clinical point of view the surrounding musculature is infinitely more important than the surrounding fibrous ring. In spite of the teaching and discoveries of embryology we still confuse under the term "base" two totally different parts of the heart—namely, the commencement and end of the cardiac tube. The conical shape of the heart—its apex and base—we assume as axiomatic and incapable of explanation. We describe the walls of its chambers as if they were rigid, overlooking the fact that they are composed of a pulsating musculature arranged so as to produce definite movements by which their contents are propelled.

So far my argument has been to show that our progress in real practical human anatomy during the nineteenth century has not been so great as is generally supposed, the lack of progress being due in the first place to our acceptation of "descriptive" anatomy as the real anatomy, and, in the second place, because side issues have been allowed to draw anatomists away from their real work. But it might be urged that the defects I see in modern anatomy are the result of the separation from it of physiology—a separation necessitated by the growth of knowledge. That a separation was necessary I fully admit, but that the dividing line should have been drawn where we now find it has proved, as I have just shown, a great misfortune, not only for the progress of anatomy but also of physiology. It is an artificial line established by Winslow's unhappy facility of description. Between anatomy and physiology has been left a no man's and and yet one of great importance to medical men. I refer especially to the muscular mechanisms of the body—the mechanism of respiration, circulation, digestion, deglutition, micturition, and locomotion, subjects at present indifferently taught and indifferently understood, because the man who teaches the action has forgotten the structures that are involved, and the man who describes and knows the structures has not troubled to discover how they act. In our school, as in many others throughout the country, the gap between anatomy and physiology, which tends to widen, has not been felt because of the harmonious workings of the two departments, yet I think the time has come when a reconsideration of the present dividing line is necessary in the interests of all concerned.

There are many reasons that make a reconsideration of the present scope of anatomy urgent. There is, in the first place, the enormous growth of physiology; already those that teach that subject find its present scope beyond the powers of one teacher. There is, in the second place, the necessity of finding more time for the subjects absolutely essential to the profession of medicine—the old but ever-growing subjects of medicine, surgery, and midwifery; the newer subjects—pathology, bacteriology, pharmacology, hygiene, and special diseases. Something has to be unloaded to make proper room for those, and we anatomists, who like thrifty housewives have treasured everything, have to unload our share and, for my part, I will willingly let go much of that material we dragged ashore in our close-meshed descriptive net. If to the splendid basis of descriptive anatomy we have now at our disposal we were to add the practical spirit of the eighteenth century anatomists I feel certain we should secure a future of great prosperity for anatomy.

A Lecture

ON

THE STUDY OF EMBRYOLOGY.

Delivered at King's College, London,

BY PETER THOMPSON, M.D. VICT.,

PROFESSOR OF ANATOMY AT THE COLLEGE.

GENTLEMEN,—It may be a commonplace remark, but it is nevertheless true, that in tracing the evolution of the present state of knowledge of any subject one engages in a task which is at once illuminating and stimulating. How interesting it is, for example, to come across such observations as those of Rathke and Valentin, two distinguished men who lived in the first half of the last century and who clearly saw the great future which lay before the science of embryology. Thus Rathke, in 1832, commences his anatomical and philosophical researches, &c., with a praise of our subject: "In order to understand the laws which lie at the foundation of animal creation," he says, "one must not look only at the fully-developed animal but also turn attention to those in process of development. For here you see an organ gradually converted from a simple into a complex one. Moreover, it stands to reason that one is able to recognise the laws of creation sooner whilst they are actually being carried on than when they are completed." And Valentin, in 1835, remarks: "Almost all physiologists and anatomists who have been active and celebrated in our time have directed their attentions to the development of the individual as opposed to the problem of the relationships of the animal world—i.e., comparative anatomy. Both together are the foundation on which the true and genuine conception of animal life must be based."

In tracing the history of embryology we see that although the study of the actual development of animals during their evolution from the egg has attracted attention from very early times, little advance was made until comparatively recent years. Indeed, it is only within the last 20 or 30 years that the enormous powers of embryology as an instrument for unravelling the problems of early growth have been manifest, and one can clearly see the main factors which have contributed to this change of affairs: the promulgation of the cell theory, the invention of the microtome, Darwin's theory of the origin of species, and lastly the many observers who, with modern weapons, have explored the little-known country hitherto visited by a small but valiant band.

Striking, therefore, as were the advances made in all branches of biological inquiry during the nineteenth century, in few was this advance more marked than in that of embryology. From its commencement, through the genius of Harvey, Haller, and Wolff in the seventeenth and eighteenth centuries, little progress was made until the early years of the nineteenth century, which through the researches of Pander and von Baer practically witnessed the birth of embryology as a science. Pander's investigations have become classical and the results of his work are to be found in our modern text-books of embryology and are taught to-day. Through the interest thus associated with Pander and his time it may be recalled that it was in 1817 that he deluded scholars into *mistaking* the shadow for the substance. A system of knowledge which settles home too easily in one's understanding is just the knowledge to be accepted with scrutiny. Winslow purposely abstained from attempting to explain the meaning of the structures which he described, *proposing to relegate* all that related to function to another volume. In so doing he emasculated anatomy; but the *system* he initiated prospered abundantly, and at the end of the eighteenth century, in the hands of his able follower Bichat, it came to be regarded, in France at least, as the ideal conception of anatomy.

In the opening years of the nineteenth century we can see the French influence at work in the British schools. In 1804 and 1807 appeared Sir Astley Cooper's famous folios on Hernia. They differ totally in spirit from the anatomical works of the previous age—those of Hunter and Monro. They are minute, elaborate, and rather irksomely accurate descriptions of parts; he never stops to ask why the parts are so arranged but is content to have described them. The "London Dissector," a popular guide in the dissecting-room during the earlier part of last century, is a purely descriptive work with the merit of brevity. The "Dublin Dissector" is unmistakeably founded on the teaching of Bichat. When in 1828 Jones Quain published the first edition of that famous work, which has had many rivals but, in my opinion, no equal, he quotes with commendation the *system* of description enunciated by Béclard—namely, that in dealing with a structure the *following* order should be observed: (1) form and outline; (2) situation and relationship; (3) direction of its axis; (4) size; (5) physical characters; (6) anatomical composition; (7) chemical composition; (8) secretions; (9) properties during life; (10) vital action; (11) sex and age change; and (12) morbid changes. Béclard's is certainly a comprehensive formula, but still it is a formula, and nothing is more certain than that the introduction of a formula into any *system* of knowledge whatsoever means a cessation of all rational endeavour in that system. But to see with what avidity the conception of anatomy as a "descriptive science" was accepted in Britain one must turn to the *writings of that ill-starred* whirlwind, the brilliant anatomical demagogue, Robert Knox of Edinburgh. It seized him with all the force of a revelation; in season and out of season, by translation of French treatises and popular lectures, he preached the adoption of the methods and ideals of Bichat and Cuvier as the salvation of British anatomy. If other British anatomists adopted these ideals more quietly than Knox they were *nevertheless* sound converts and by the middle of the nineteenth century we see the French *formularies* brought to perfection in the hands of Ward and Ellis. Throughout the whole of the nineteenth century British anatomists built on the plan designed by the French anatomists of the eighteenth century. That this plan has provided a sound foundation for the accumulation and systematisation of anatomical *fact no one* can deny who is familiar with our magnificent modern text-books, wherein, at a length of some 800,000 or 900,000 words, the medical student is presented with an exhaustive description of the *dead* human body. If we had remained true to the ideals of the earlier British anatomists they would have portrayed a picture of the *living* human body.

While the *general trend of anatomy* in this country during the nineteenth century was mainly determined by the acceptance of the French ideals, yet *even* a brief account would be altogether misleading unless other influences are noted which came to bear on British *anatomists* and determined the direction of their observations. In the opening decades of the nineteenth century Cuvier's influence was *profound*. He had demonstrated to all the world that anatomy provided the data by which the members of the animal kingdom might be arranged in a natural and orderly system of groups. Anatomy, which had been the humble utilitarian drudge of medical men, was *promoted to be* the handmaid of men whose aim was pure science. Human anatomists gladly forsook the task of trying to discover the *mechanism* of the human body and set out on the high task of setting the animal kingdom in order. The methods of descriptive *anatomy*, however imperfectly they may answer the purposes of medical men, were admirably adapted for the needs of the comparative anatomist. *Owen* became the first effective exponent of the Cuvierian school in England and I know of no finer irony in fate than that the Hunterian collection which the eighteenth century master had built up to elucidate the contrivance of the human body in particular and the *organisation* of living things in general, should have been placed in the hands of one who, however brilliant his powers of description, was a believer in archetypes rather than in function. Owen's fame and name were great, and if he exercised no direct effect on the *body* of knowledge *which* we call human anatomy, yet one can see that *from* 1830 onwards he gave many anatomists a bent towards vertebrate morphology, and *thus to* some degree modified the undercurrent of *our anatomical text*.

There is a very remarkable *parallelism* between the three men who dominated anatomical work in France during the earlier decades of the nineteenth century and the three men who exercised a *similar* influence in England during the great Victorian period. Cuvier was accompanied by two men, Etienne Geoffroy St. Hilaire and Lamarck. They were interpreters of fact, and Cuvier, a *describer and classifier*, used his predominating influence to suppress them. Owen was also accompanied by two interpreters of fact; in place of Geoffroy St. Hilaire stands Huxley, in place of Lamarck, Darwin, but in England it was the interpreters of fact who proved victorious. Darwin and Huxley had a profound influence on the work of British anatomists; they brought them back to the study of the human body; evolution *provided* a key to many structures which puzzled the human anatomist. But while man's position in the animal world was being determined with great success his place in the medical world was well-nigh forgotten.

In the last three decades of the nineteenth century a movement in a new direction became general amongst anatomists. The development of the body became more and more a subject of investigation. In this movement the late Professor His exercised a predominating influence; it was patent to all that the reconstructional and modelling methods which he employed with consummate skill provided the *material for the foundation* of a *sound and* progressive system of knowledge. *In* the main His was a descriptive embryologist; *he carried* the ideals current amongst anatomists of his time into a new field of work. Far be it from me to deprecate the value of *descriptive* work in embryology or anatomy; only I would most strenuously urge, what is so frequently forgotten, that description is only the *beginning*, not the end, of all embryological and anatomical investigation.

Thus it *comes* to pass that a *young man commencing* the study of medicine in 1907, although he may obtain a truer conception of "*Man's Place* in Nature" and a *fuller* knowledge of the development of the human body than was possible for his predecessor of 1807, yet holds little or no advantage over him as regards the available stock of practical anatomical knowledge. For proof of what I maintain one may turn to the account of the heart, that *organ* which in all times has been accounted the most important in the *study and practice of medicine, given in* Bichat's "Traité d'Anatomie Descriptive"[1] and *compare* it with the descriptions given in the latest *editions of* our *modern text-book* of anatomy and it will be found that, as far as concerns the naked eye anatomy of the heart, the *one* account differs very little *from* the other; indeed, if anything, the older book gives the better working picture of the heart. The same parts are enumerated and described; in the right auricle, for instance, the student is asked to observe the openings of the *superior and inferior vena cava, but in neither* the old work nor the new is any mention made of the arrangement of the musculature round these *orifices, the* student apparently being expected to presume that they are always open. Bichat, it is true, *describes* a rounded band of musculature in the right auricle crossing in front of the superior caval orifice but of its significance says nothing. In *modern* text-books this same band is described as a crest—the crista terminalis, the very name showing how *far* anatomists have lost sight of function when they name a *contracting* band of muscle a crest. From the physiologist the modern student learns that these *orifices* are *closed during auricular* systole by the surrounding circular musculature, but when he comes to examine the human heart he will find that there is no circular musculature round the inferior caval orifice, while he will find it *difficult to believe that the* muscle round the upper orifice is sufficient for the task ascribed to it.

Having compared the best of the early nineteenth century with the best *of* the early twentieth century anatomies, let us turn *to* the account in the last *of* the truly British text-books, Bells' "Anatomy of the Human Body." From an examination of the parts the anatomist

---

[1] *Paris*, 1803.

26 years of age, he became, through Meissner's promotion to Freiburg, professor of anatomy and physiology in his native town. *Owing to his youth and natural modesty*, he was somewhat diffident of his power for carrying on the work of the two subjects, but the Chancellor of the University (Herr Peter Merian) remarked to him: "Wir haben sie ins Wasser geworfen, sie mogen nun zusehen, wie sie schwimmen" ("We have thrown you into the water, see to it that you now swim"). It is well known how brilliant his career has been and how richly his labours have been rewarded in that realm of science over which he held almost sovereign sway. His has acknowledged, however, in allusion to the remark of the Chancellor that several times in the first year after his appointment, when day by day he was engaged in preparing lectures, demonstrations, and experiments, "Der Wasser ging mir allerdings weit an den Hals herauf," or, in other words, that he often felt like drowning. He remained in the University of Basle until 1872, when he succeeded E. H. Weber as professor of anatomy and director of the anatomical laboratories in the University of Leipsic. Simultaneously with his appointment, W. Braune, Weber's son-in-law, became professor of *topographical anatomy in the same* University. These two men, differing in age by only a few days, but differing markedly in their general temperaments, became very close friends, and on the death of Braune in April, 1892, the loss was felt by His to be well-nigh irreparable. His's work was done first in the old, then in the new buildings of the institute at Leipsic. The new buildings were erected under his supervision and have become a model for successive generations. With regard to his original work, it may be said at once that he contributed valuable papers to nearly every department of anatomy, but it is as an embryologist that he is best known in this country, where his name has been familiar to every medical student during the last 20 years. In 1885 he completed the great work which he published under the name of "Anatomie Menschlicher Embryonen" and which has *formed the basis of all* subsequent text-books dealing with embryology. His's monographs and miscellaneous papers exceed one hundred in number. He passed away in May, 1904, in his seventy-third year, the promise of his earlier days being amply fulfilled, and he has left a legacy of enormous scientific value to his successors.

To the medical student anatomy very often means simply human anatomy. But this is anatomy in a very restricted sense. Anatomy when regarded as a science includes embryology and comparative anatomy, whilst anatomy essential to the physician and surgeon is really applied anatomy. The three subjects, human anatomy, comparative anatomy, and embryology, constitute what is known as morphology and the specialist in anatomy of to-day must be acquainted with all three. Similarly a well equipped anatomical institute must contain laboratories for the prosecution of research in these three directions. Moreover, in view of the supreme importance of a precise and accurate knowledge of the anatomy of the human body and the limited time for the study of the preliminary and intermediate subjects, it is not surprising that the medical student should have *less* regard for the study of embryology and comparative anatomy than for human anatomy. But practical embryology is a fine training for anyone who proposes to enter the medical profession, whether he intends to be a surgeon, a physician, or a general practitioner. The patience, skill, and thoroughness necessary to work successfully through an embryo train his powers exactly in the right direction, and in some of the universities in Germany medical students who have the time and inclination are encouraged to take up work of this class.

We have seen how in the prosecution of embryological research serial sections became imperative. Odd sections taken here and there and studied apart instead of in conjunction with neighbouring sections could only lead to speculation and error. Even with a complete series of sections of an embryo it is often difficult to read them correctly; it is therefore necessary to visualise them in some way and this is now done by reconstruction methods. If you will pardon the simile, it might be said that just as by means of a piano the beauties of a piece of music in manuscript can be rendered manifest, so by reconstruction in wax, one can visualise and make manifest the form of the embryo from a series of microscopical sections. It is *easier* to appreciate music when it is actually played on an instrument and it is easier to interpret and appreciate microscopical sections of embryos when they are reconstructed in wax in the form of a model The employment of serial sections therefore leads naturally enough to the discovery of reconstruction methods. To Professor His must be given the credit of perceiving the *need of reproducing in some way the bodily form of the* object which had been cut into sections. This necessity he met by his "*projective reconstruction method.*" May I describe this very briefly? He employed millimetre paper, each line of which was taken to represent a section. Beginning from a base line, the back in case of a profile reconstruction, and the middle line of the body in case of a frontal reconstruction, he measured along the lines of his paper the distances of any organ as shown in the drawings which he made of the sections enlarged, say, 100 times. When he had *entirely worked through his series of sections* the corresponding points on the lines were joined up, and thus was projected on paper the profile form of the object with which he was dealing magnified 100 times. After working through the sections of the embryo in this most exact way he set to work to freely model the embryo in clay or wax. That is to say: he had obtained such a knowledge of the embryo from working through the serial sections that he was able to take some clay and make a model of the form he conceived the embryo to be, controlling all the time the size and distances, &c., by means of callipers and references to the enlarged drawings of the sections. *In this way* many well-known models were made which have become familiar to all students of biology and anatomy throughout the world, and I would mention particularly the series of models illustrating the development of the chick, the salmon, and the human embryo. How necessary it was to visualise the sections in some such way as this is shown by the fact that Krieger quite independently thought out the same idea. He employed *the same methods* in the study of the central nervous system of the crab and about the same time, or a little later, other methods were suggested which served the same purpose. His's projective reconstruction furnished drawings and freely modelled objects. In the making of the models he has had no successor. The art required a particularly *high technical gift* to overcome the many obstacles and to neutralise the many sources of error. Moreover, a new method was suggested by Professor Born which entirely displaced it. This was, after various *modifications*, eventually extensively employed and was utilised by *His himself in* his later years.

Before proceeding to give an account of Professor Born's method of reconstruction by means of wax plates I wish to refer to a very interesting point in connexion with the *history of the method*. Born's method was briefly announced in 1876 and was fully described by him in 1883, and there seems no doubt that the credit of first publishing the method rightly belongs to him. But when in conversation recently with the librarian of the Royal Microscopical Society I was greatly interested to hear that something similar had been published quite independently in England about the same time. On Jan. 24th, 1879, Mr. E. T. Newton read a paper before the members of the Quekett Microscopical Club explaining how he had made a model of the brain of the cockroach. He evidently had experienced the *great difficulty* of visualising the form of objects cut into serial sections, for he remarks in his paper: "Anyone who in working out structures by means of sections has endeavoured to trace the various parts through a series of sections will understand how difficult it is to *keep in mind* the structures seen in each, so as to picture to himself the form of any part when entire. And still more difficult is it to convey to others the knowledge which one has gained by the examination of such a series." In order to explain to the members of his club the details of the structure of the brain as obtained by an examination of the sections, Mr. Newton made plates of soft pinewood, each one-eighth of an inch in thickness, each plate corresponding to a section and cut out by a saw in the form of the section. When these were piled one on the other an entire view of the brain enlarged was obtained in the form of a *wooden model*. There seems no doubt that Mr. Newton thought out quite independently the main principle underlying the method of reconstruction by plates, though it was some three years later than Born's first publication.

[A demonstration was then given of the details of Born's method of reconstruction by wax plates, illustrated by model- and *lantern slides*. In brief, this may be described as follows. The sections of the embryo are drawn on a thin sheet of paper either by the aid of a camera lucida or a projection apparatus and special drawing board at a magnification of 25, 50, or 100 times the size of the section, as desired. Each sheet of paper is then placed on a stone, and von Baer proceeded to Würzburg to work under Döllinger, and as a result of his advice and influence Pander carried out important researches on the development of the chick. Thus was formed, as von Baer himself has told us, a noteworthy association, destined to have far-reaching results, between Döllinger, the grey-haired veteran in physiological researches, the youthful Pander, burning with zeal for science, and the incomparable artist Dalton. Von Baer was so impressed with Pander's zeal that he, too, determined to devote himself to the pursuit of embryological problems. In 1819 he proceeded to Königsberg, and for several years enthusiastically applied himself to the elucidation of the developmental phenomena of animal organisms. The first volume embodying the results of the monumental work was published in 1828, entitled "Observations and Reflections on the Development of Animals." The second volume was published in 1837, and a third one in 1888, after his death. These publications contain not only the main results of Baer's scientific inquiries but also form the basis on which all modern embryology practically rests. Referring to them, Huxley justly observes: "Baer's book on the development of animals contains the deepest and soundest philosophy of biology and zoology which has ever been presented to the world," and Kölliker is in agreement with him when he says "Baer's works ought, on account of their richness and excellence of facts, the erudition and the magnitude of the developmental observations, certainly to be regarded as the best which the embryological literature of all times and all nations has to show." Amongst Baer's observations one stands supreme—viz., the finding of the mammalian ovum in 1827. This discovery was published in a short pamphlet entitled "De Ovi Mammalium et Hominis Genesi," and he subsequently demonstrated before a society of natural philosophy in Berlin preparations showing the extremely small mammalian ovum inclosed within the Graafian follicle.

But besides von Baer, to whom must be ascribed the first place amongst the workers in embryological science, many others were engaged about this time in similar problems in Germany and other countries. In Germany, Oken and Meckel, Carus and Rathke, Johannes Müller, Huschke, and Siebold; in France, Butrochet, Prévost, and Coste; in England, Allen Thomson, Wharton Jones, and Martin Barry; in Italy, the famous Rusconi—each made valuable contributions to the rapidly growing science.

Here let me say a few words about Allen Thomson, whose son we have amongst us as Vice Principal of this College. He is rightly regarded as the father of embryology in this country. He published as early as 1839 papers dealing with early human embryos, and even before this date—i.e., in 1831—he proved by means of sections cut by hand that the main aorta is formed by the median fusion of two vessels previously separate, a most interesting and noteworthy discovery. Moreover, we ought not to forget that prior to 1830 little was known of embryological science in this country and that between 1830 and 1845 the only anatomist who was devoting himself to human embryology was Allen Thomson and that it was in this field that he won his laurels. It is an interesting fact and shows the bent of his mind that at 21 years of age he published a paper on the development of the vascular system, and throughout his life embryology continued to be the favourite subject of his study and researches.

Now may I remind you that the work done in the field of embryology in the first half of the century was done before the discovery of the microtome, an instrument which, though universally used at the present day, is of comparatively recent introduction. Indeed, so little advance had been made in methods of technique that Pander and von Baer practically used the same methods as Haller and Wolff had done in the century preceding. I gather from a paper by Professor Minot that "sections, though more or less used in the early half of the century, were not much relied upon until the second half of the century had been reached, and we may say that it was approximately about 1860 that section cutting began to come into favour among microscopists. But it was not until 1874 that microtomes began to make their way." How then did the old embryologists arrive at their conclusions? An interesting sidelight is thrown on this question by Huschke mentioned above. This observer published in 1832 an account of the formation of the otic vesicle and the lens. As he studied the growth of the eye in the chick he noticed in the middle of the eye vesicle a little spot which he imagined to be the anlage of the lens. He explored it with a fine hair, with the point of which he slipped into an opening. "Now I am free from all doubts," he says. "I knew at once how the lens, the lens capsule, and particularly the labyrinth of the ear were developed. I saw they were formed from a depression or invagination of the external skin."

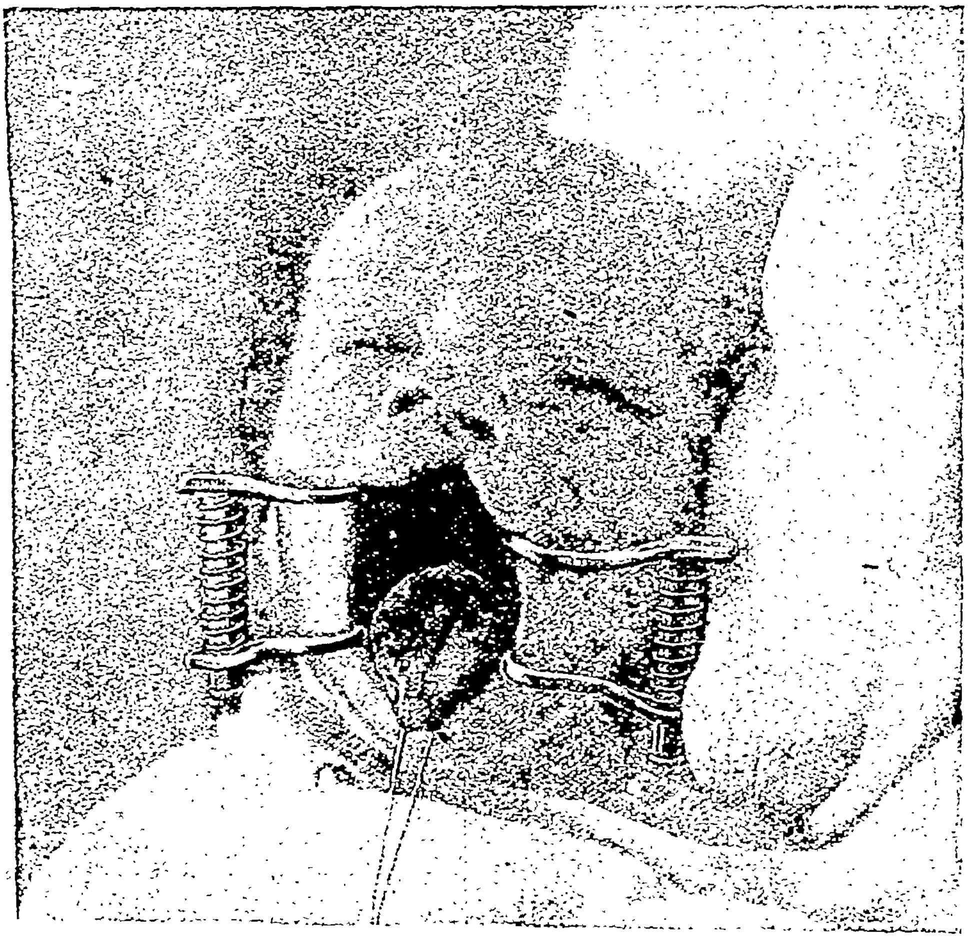
And so with such simple apparatus as a magnifying lens, scissors, knife, and razor the pioneers of embryology pursued their way. Then came the wonderful discovery of Schwann that all animal tissues were composed of cells. With this new impetus it is not surprising to find that embryology was for a time included as a branch of physiology. The delicate methods employed in histological research were just those necessary for the study of young embryos and the subject was therefore taught by physiologists. But the anatomists soon woke up; they saw a new world ready for exploration, a world which for them offered a solution of many completely unintelligible anatomical facts. It was therefore absolutely essential for them to master the new science and with as little delay as possible they entered into possession of their kingdom. Schwann's discovery ultimately had a transforming influence on embryological technique. The methods of the old teachers were no longer sufficient. It was recognised that what the atom was to the chemist the cell was to the embryologist, and nothing short of thin sections, high power of magnification, and elaborate methods of staining would suffice. It was imperative that there should be some means of obtaining thin even serial sections and this demand was soon supplied by the genius of His.

The first microtome, the instrument by which serial sections of objects are obtained, which at all corresponded in principle to those in use at the present day is apparently the one described by His in 1870. Previously to that time a form of microtome known as Valentin's double knife had been employed, but the principle of this was altogether different from that of the microtome in use now. The essential points of His's microtome were a mechanically moved razor and an arrangement for mechanically advancing the block, and although the means of obtaining these essential points have in later years been improved they constitute the basis on which all microtomes are constructed. I think it may not be without interest to quote the following statement made by His, for nothing could better illustrate the enormous progress that has been made since 1870. Professor His, speaking of the advantages of his own instrument, said: "I have used the instrument since 1866 and I have prepared during this epoch (i.e., four years) over 5000 sections." My assistant Weston has recently cut, by means of a modern microtome, nearly 5000 serial sections in a fortnight in the odd intervals snatched during the day from the ordinary routine work of the department.

Striking as was the work of Pander and von Baer in the earlier part of the century, in no less degree was that of Wilhelm His in later years. His influence on embryology has been incalculable, and if I were to mention particularly one of his researches in preference to others, it would be the wonderful monument of neurological investigation, which stands unique. Indeed, so far-reaching has the influence of His's life been on all subsequent workers in the field of embryology that it may not be out of place to give a brief sketch of the career of this remarkable man.

Wilhelm His was born in Basle in 1831 and it was there that he commenced his medical studies in 1849. In the year following he moved to Berne where he had some relatives connected with the university of that city. Here Theile taught anatomy, Valentin physiology, and Bernard Studer geology. From 1850 to 1852 His was in Berlin, where he came under the influence of Johannes Müller and Remak. He was much impressed by the great biologist, whose lectures on human and comparative anatomy were at that time perhaps unequalled. Indeed, Professor His has left it on record that the first lecture of J. Müller which he attended was a perfect revelation in the way of teaching and erudition. It was, too, from Müller and Remak that he learnt the elements of embryology, and thus laid the foundation of the great work which he was destined to carry out in the future. From Berlin he went to Würzburg, where he stayed three terms (1852–53). Here he came under the notice of Virchow and worked in his laboratories. Shortly afterwards, in 1854 he returned to Basle to complete his examinations and then he proceeded to Paris. In Paris he met Claude Bernard and Brown-Séquard, and worked for some time in the laboratory of the Collège de France. In 1857 he became a privat-docent under Professor Meissner, and in the same year, when only which I perform for cleft palate is to close in the interval between the edges of the cleft by muco-periosteum in the case of the hard palate and by mucous membrane and submucous tissue in the case of the soft palate. In the latter every care is taken to avoid damage to the muscles and nerves, the interval between the segments of the palate being filled in by a soft elastic curtain made up of opposing layers of mucous membrane and submucous tissue. If hare-lip exists the cleft or clefts in it are closed at the same time as the cleft in the palate. This is done for three reasons. The first and most important is that the soft parts which are removed necessarily from the margins of the lip may be of the greatest service in completing the closure of the anterior part of the cleft. The second reason is that I find that postponing the hare-lip operation for a time reduces the chances of union. The third reason is that the sooner the pressure of the complete lip is brought to bear upon the segments of the upper jaw as well as upon a displaced premaxilla, should it exist, the more rapid is the approximation of the bones forming the *front of the cleft* and the restoration of the premaxilla to its normal relationship. The muco-periosteum covering the premaxilla is also useful in helping to close the cleft.

FIG. 1.



Shows gags in position *for operation*, the tongue being drawn forward by a silk thread passed through the tip.

Practically the flap formation employed to close in the hard and soft palate resolves itself into two methods. If the soft parts overlying the edges of the cleft are thick and vascular a flap is cut from the mucous membrane, submucous tissue, and periosteum *of one side*, having its attachment or base along the free margin of the cleft. The palatine vascular supply is divided while the flap is being reflected inwards and it depends for its blood-supply on vessels entering its attached margin. The *mucous* membrane, submucous tissue, and periosteum are raised from the opposing margin of the cleft by an elevator, an incision being made along the length of the edge of the cleft. The reflected flap with its scanty supply of blood derived from small vessels in its attached margin is then placed beneath the elevated flap the blood-supply of which is ample and it is fixed in position by a double row of sutures. In this manner two extensive raw surfaces well supplied with blood and uninfluenced by any tension whatever are retained in accurate apposition. If, on the other hand, the cleft is too broad to admit of its safe and perfect closure in this manner, one flap, comprising all the mucous membrane, submucous tissue, and periosteum, on one side is raised except at the point of entry of the posterior palatine vessels, while the soft parts on the opposite side are raised in a flap from which the posterior palatine supply has been excluded and which turns on a base formed by the margin of the cleft. Here we have a mobile, well-vascularised flap which can be thrown as a bridge in any direction and can be superimposed on the flap of the opposite side, the closure being necessarily rendered complete by flaps *from the edges* of a hare-lip. Obviously the surgeon must be guided entirely by his instincts and experience as to the best mode of closing any particular cleft, and this description of methods must be of necessity of a general *character*.

As time goes on the damage done to the temporary teeth by the separation of the superjacent mucous membrane becomes steadily greater. Still, this is a matter of no moment as compared with the importance of the early closure of the cleft, since the milk teeth are often unsatisfactory in cases of cleft palate apart from operative interference, while the permanent teeth escape damage from it if undertaken *sufficiently early* in life.

I now purpose to describe in detail the measures by which the principles that I have laid down for the closure of clefts are applied. In Fig. 2 I have attempted to indicate such as is used in lithographic work, and melted wax is poured over it. When partly solidified it is well rolled, the thickness of the wax being determined by two brass strips, one on either side of the sheet and either one-half a millimetre or one millimetre in thickness, according to a calculation based on the thickness of the section and the magnification of the drawing. In this way wax plates are obtained from which the shape of each drawing can be readily cut by a sharp knife. These are all piled one on the other and when completed give a reproduction in wax of the form of the embryo magnified in accordance with the number arranged at the time of drawing.]

The special features of Born's method of wax plates are its comparative simplicity and its accuracy. It largely excludes the personal element in the making of the model and does not demand a great degree of technical skill or dexterity. Patience, thoroughness, trustworthiness, and enthusiasm, with dogged perseverance are the attributes necessary for him who will reconstruct in wax a complete model of a human or any other embryo in the early stages of development. As I said before, the training is an excellent one and the experience gained is invaluable for carrying on future work in whatever branch of medicine that work is to be done. I hope that the time is not far distant when some of our students who have the opportunity and the inclination will be prepared to take up work along these lines. They will not regret it. "*The harvest truly is plenteous, but the labourers are few.*"

Most of you will doubtless remember the following words of the Right Hon. Lord Avebury in his charming book "The Pleasures of Life": "There never was a time when thought was freer or when modest merit and patient industry were more sure of reward." How very applicable these words are when applied to the study of embryology by means of modern methods. We must not, however, regard embryology "as a master-key that will open the gates of knowledge" and remove all the difficulties in our way without great efforts on our part. As A. M. Marshall remarked in one of his lectures: "It is rather to be viewed and treated as a delicate and complicated instrument, the proper handling of which requires the utmost nicety of balance and adjustment, and which, unless employed with the greatest skill and judgment, may yield false instead of true results. We are indeed only just beginning to understand the real power of our weapons and the right way of employing them, and in the future embryology, especially when studied in connexion with palæontology, may be confidently relied on to afford a far clearer insight than we have yet obtained into the history of life on the earth." Born's method is obviously a most valuable aid in embryological research and is almost universally used in the German universities. In England, up to the present, it has not been much in evidence and there is, I think, a great future for an embryological school in London. If our University could see its way to provide such an institution, properly equipped and endowed, there might be a better chance of contributing our fair share towards the elucidation of the multitudinous problems in embryology which are still waiting solution. A great deal has already been done in this country but there is an enormous amount still to be accomplished, and this can best be dealt with by providing special facilities for those who are anxious to take a share in the task.

Much has been made in the past of the similarity in external form and internal structure which characterises the embryo of man and other animals in the early stages of development. That this is an embryological truth of the first magnitude no one will deny, and Haeckel, Darwin, and Huxley have drawn important deductions from this striking law. Von Baer himself having three unnamed embryos in his collection could not say in which group of vertebrates, reptiles, birds, or mammals, they were to be placed, and a still more striking illustration is afforded by the remarkable controversy which was kept up for many years over Krause's famous embryo. "In 1875," Marshall tells us, "Krause described an early human embryo which appeared to differ from all known human embryos in having a large vesicular allantois like that of a chick or a reptile instead of the allantoid stalk by which the human embryo is normally connected with the chorion. The peculiarity with regard to the allantois was so marked that doubts were at once raised as to the embryo being really a human one, and Professor His asserted roundly that Krause must have made a mistake and that his specimen was a chick embryo and not a human one at all. An ardent, almost furious, discussion arose and continued for many years; indeed, it was only in 1892 that the points at issue were finally put at rest, and it was shown that while Krause was right in describing his embryo as a human one he was mistaken in regard to the supposed peculiarity in the allantois, the bladder-like vesicle which he took for the allantois being merely a pathological dilation of the allantoic stalk."

There seems, however, very good reason for believing that when the early embryos of man, ape, dog, rabbit, and other animals are reconstructed and enlarged in the same way as the human embryo shown this afternoon and compared there will be little or no difficulty in distinguishing one from the other. I anticipate that as other models are made by Born's method certain characteristics will become evident in each series—characteristics difficult to recognise and appreciate before the enlargement is carried out. I wish I could obtain embryos of the gorilla, chimpanzee, and orang-outang of approximately the same age as the human embryo, the model of which is on the table. If these could be reconstructed in wax enlarged, say, 100 times, I would not be surprised if certain differences became apparent, from a study of which it would be possible to realise that the human embryo as early as the third week of development possesses certain characteristics by which it can at once be separated from those to which it is, zoologically speaking, nearest akin.

I trust, therefore, it is clear that the evolution of embryology as a science took place to a greater extent in the nineteenth century than in the centuries before. It is, indeed, at the beginning of the twentieth century still a comparatively new kingdom with vast territories still waiting to be explored. There is no royal road to it, only the strait gate and narrow path. There are few excitements; only the daily round and common task. There are no rewards as the world would count them; only the joy and gladness which come from a close communion with Nature and the chance of wresting from her some of her secrets. In "Sartor Resartus" Carlyle has sounded the call afresh which men have heard all down the ages, "Produce! Produce! Were it but the pitifullest infinitesimal fraction of a Product, produce it in God's name, 'tis the utmost thou hast in thee: out with it then." The torch of science burns brighter than ever to-day, and who can foresee what it shall illumine? As the illustrious von Baer eloquently expressed it: "Die Wissenschaft ist ewig in ihrem Quelle, unermesslich in ihrem Umfange, endlos in ihrer Aufgabe, unerreichbar in ihrem Ziele" ("As for science, its source is eternal, its comprehension is immeasureable, its task is endless, and its final goal is unattainable").

S. Minot ("The History of the Microtome"); and (4) A. M. Marshall ("Lectures and Addresses"). The sketch of His's life is taken from the obituary notice which I contributed to the *British Medical Journal* in May, 1904.

THE MODERN TREATMENT OF CLEFT PALATE.

BY W. ARBUTHNOT LANE, M.B., M.S. LOND., F.R.C.S. ENG.,

SURGEON TO GUY'S HOSPITAL; SENIOR SURGEON TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET, LONDON, W.C.

IN THE LANCET of Feb. 22nd, 1902, p. 498, my teaching on cleft palate, together with the technique of my operative procedure, was explained, and I now propose to submit with as little repetition of my former communication as possible my present-day practice in regard to the more difficult cases of cleft palate.

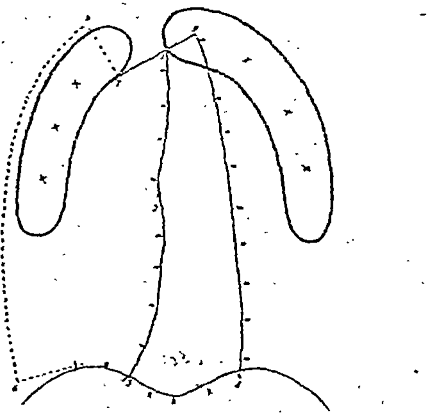
In early infancy it is possible to provide a well vascularised thick flap which is practically three times as broad as can be obtained when the teeth have begun to encroach materially on the mucous membrane or to perforate it, since the muco-periosteum covering the under and the outer surface of the alveolus can be made to form the outer two-thirds of the flap. In Fig. 1 there is represented an infant with gags in position for operation, the tongue being drawn forwards by a silk thread passed through the tip. The figure gives a good idea of the space gained for operating.

The general principle underlying the various operations

4 the posterior free margins of the reflected flaps are shown joined by sutures.

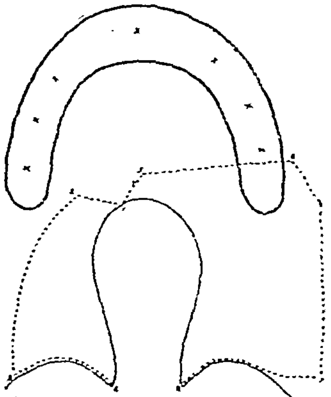
Should the cleft involve only the soft palate, as is shown in Fig. 7, the same method can usually be applied. The uvula on the left side of the diagram is pulled forwards so that the upper surface of the palate is exposed, and an incision is made from 1 to 2 to 3 to 4, through the mucous membrane and submucous tissue, which are dissected off the subjacent parts inwards to the margin of the cleft. From the area of the soft palate corresponding to the right portion of the diagram a flap is raised from its under surface by an incision from 1 to 5 to 6 to 7 to 8, and is reflected inwards to the margin of the cleft.

FIG. 6.



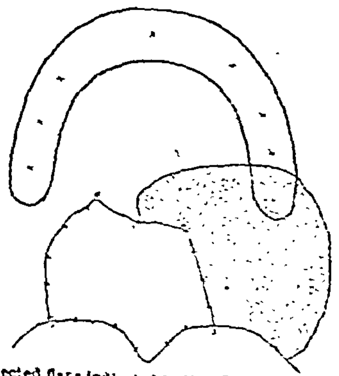
Flaps indicated in Fig. 5 shown in position.

FIG. 7.



Broad cleft of soft palate, incisions being indicated by dotted lines.

FIG. 8.

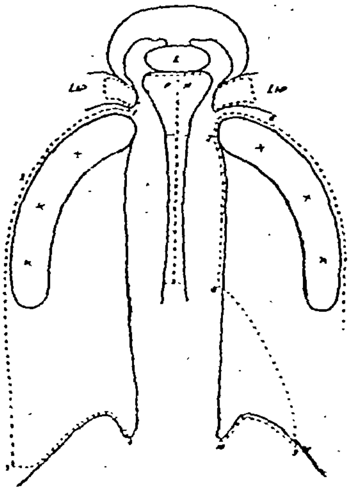


Reflected flaps indicated in Fig. 7 shown in position.

Fig. 8 shows the flaps sutured firmly in position, the darkened area representing the portion of the palate left uncovered by mucous membrane. The deep sutures uniting the edge of the flap obtained from the under surface of the palate on the right side to the raw upper surface of the palate on the left side are indicated between 6 and 7, while along 1. 2, and 3 are shown the sutures connecting the edge of the flap reflected from the upper surface of the left side of the palate to the raw under surface of the palate on the right side. Between 7 and 3 are the sutures connecting the posterior free edges of the flaps. The terms right, left, refer to the diagram and not to the body. I would point out that within a fortnight or three weeks any raw surface left becomes so perfectly covered in by new tissue as almost to defy differentiation from the adjacent mucous membrane.

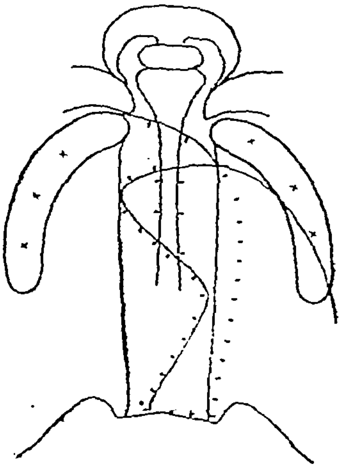
The application of the combination of reflected and pivoting flap is well illustrated by Fig. 9. This is intended to represent a double cleft palate with the premaxilla (P M) lying well in front of the level of the alveolar arch and fixed to the under surface of the tip of the nose, L being the small mesial segment of lip fixed to the anterior surface of the premaxilla. The reflected flap is obtained by an incision extending from 1 along the outer aspect of the alveolus, through 2, and on to 3, when it bends inwards along the free margin of the soft palate to the uvula 4 The pivoting flap is obtained by an incision from 5, along the outer aspect of the alveolus, through 6, along the margin of the cleft in the hard palate from 7 to 8, along the upper surface of the soft palate to 9 and then to 10. The area of mucous membrane corresponding to the triangle 8, 9 and 10 is raised and reflected inwards. The area of muco periosteum included in 5, 6, 7, and 8 is raised from the subjacent bone except at the point of entry of the

FIG. 9.



Complete cleft with double hare-lip.

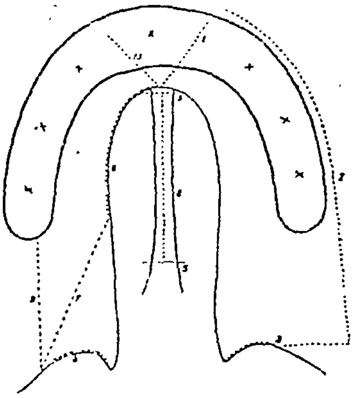
FIG. 10.



Large flaps indicated in Fig. 9 in position.

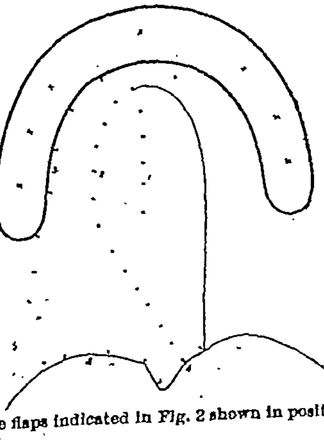
diagrammatically the details of the first method which I have described. It is intended to represent the roof of the mouth of an infant, showing a broad cleft involving almost the entire palate. The position of the alveolus is indicated by the three crosses X X X. 1 represents the incision which extends forwards and outwards through the muco-periosteum from the anterior limit of the cleft and which passes over and beyond the alveolus to its outer surface; while 2 commences at its outer limit and runs back along the outer surface of the gums about the junction of the cheek and alveolus. An incision (3) is then made from its posterior extremity along the free margin of the palate to the uvula. The flap included between these incisions is raised from the subjacent structures. It happens not uncommonly in the type of cleft palate illustrated by Fig. 2 that the septum presents a free margin which extends almost, if not quite, to the level of the cleft. In these cases I make an incision (4) through the mucous membrane and periosteum or perichondrium along the middle line of the septum with two small transverse incisions (5) at either end and turn down laterally the narrow flaps so formed, leaving the cartilage or bone bared and exposed. By placing the flap, which has been raised, in position, the line along which it will rest on the septal margin can be readily defined. With a sharp knife the surface of the reflected flap is denuded of its covering of mucous membrane along the area of impact. By a series of sutures perforating the superjacently imposed flap and the margin of the septum if it be not too hard, or the flaps of muco-periosteum if the edge be bony, the reflected flap is pinned securely to the septum. 6 shows the incision along the free margin of the cleft continued as 7, obliquely outwards and backwards along the upper surface of the soft palate. The incision 8 extends from the posterior limit of 7 along the lower free margin of the soft palate to the tip of the uvula and the incision 10 forwards and outwards from the anterior limit of 6 on to the alveolus. This last incision facilitates the raising of the flap on this side and of the introduction beneath it of the reflected flap from the opposite side. After the muco-periosteum external to the incision 6 has been raised from the bone, the soft palate is freed from the posterior margin of the hard palate and the mucous membrane on its upper surface turned outwards to the position of 9.

FIG. 2.



A broad cleft involving almost the entire palate. The incisions indicated by dotted lines.

FIG. 3.

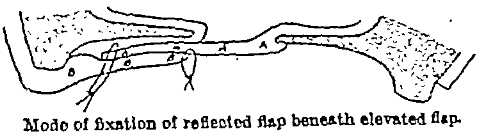


The flaps indicated in Fig. 2 shown in position.

In Fig. 3 the flaps are shown in position. The sutures along the line 1 represent those attaching the septum to the reflected flap. Those along the line 2 show the sutures which unite the free edge of the raised flap to the under surface of the reflected flap, those along the line 3 anchor the edge of the reflected flap, and those along the line 4 connect the flaps where they form the free margin of the new soft palate.

In Fig. 4 is illustrated the method of fixation of the reflected flap A A A A beneath the elevated flap B B B. The left portion of the diagram shows the flap raised from the bone through an incision along the free margin of the cleft while fixed to it by a double row of sutures is the reflected flap which has been separated from the roof through a marginal incision along the outer aspect of the gum.

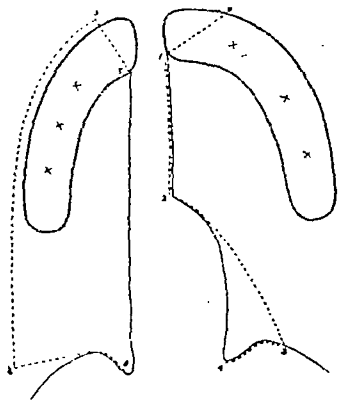
FIG. 4.



Mode of fixation of reflected flap beneath elevated flap.

Another common type of cleft palate in which the same method is frequently applicable is that illustrated in Fig. 5. The cleft in the hard palate is to one side of the mesial line where the septum is formed continuous with the margin of the cleft. The cleft in the soft palate is much broader owing to its *inclination* towards the side containing the septum. The alveolus, which is cleft also, is represented by three crosses—X X X. The reflected flap is obtained from the segment of roof, shown in the left portion of the diagram, by an incision extending from 7 to 5 to 6 to 8. The mucous membrane, submucous tissue, and periosteum are raised from the bone and aponeurosis of the soft palate. On the other side an incision is made from 9 to 1 along the edge of the cleft to 2, along the upper aspect of the soft palate to 3, and from 3 to 4. The triangular area of mucous membrane and submucous tissue included within the triangle of flap on the upper surface of the soft palate is reflected inwards to the free margin of the cleft, while the muco-periosteum is raised from the bone by an elevator and scissors introduced through the incision 1 to 2. The reflected flap is then placed beneath the elevated flap, and is retained firmly in position by a double row of interrupted sutures.

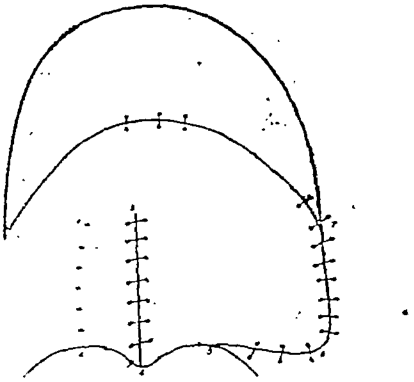
FIG. 5.



A type of complete cleft, the incisions being indicated by dotted lines.

Fig. 6 shows the flaps sutured firmly in position. Along 9 to 4 are indicated the deep sutures which pass through the margin of the reflected flap and perforate the superjacent elevated flap, while those along 1, 2, and 3 represent the superficial sutures uniting the edge of the elevated flap to the adjacent under surface of the reflected flap. Along 3 to it is impossible to close the whole length of the cleft by one single operation.

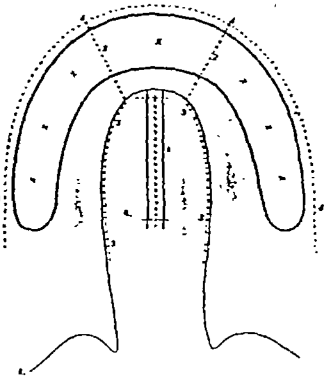
FIG. 15.



Reflected and pivoting flaps in position.

Fig. 16 illustrates such a condition. The cleft is a very wide one and it is found inadvisable to attempt to close it by the reflection of flaps in the manner already described. An incision is made along the entire outer aspect of the gum along the line indicated 1, 4, 4, 4, 4. Two are made along the direction of 2 and two others along the free inner margins of the cleft along dotted lines 3, 3. Flaps are also separated from the septal margin.

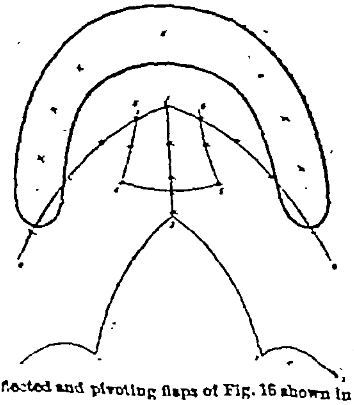
FIG. 16.



Broad cleft of hard and soft palate.

The flap included between 1 and 2 on either side is turned back, great care being taken of its posterior attachment, which is usually very thin. The flaps comprised between 2, 3, and 4 are raised from the bone from before backwards, care being taken to avoid any damage to the descending palatine vessels. These flaps are then displaced inwards as in Fig. 17, upon the subjacent flaps 3, 4, 5, 6, the margins of which are united by sutures to the superjacent pivoting flaps 1, 2, 7, 8. The apposing margins of the pivoting flaps are then sutured together and to the subjacent mesial flap and, if possible, to the septum also along the line 1, 2.

FIG. 17.

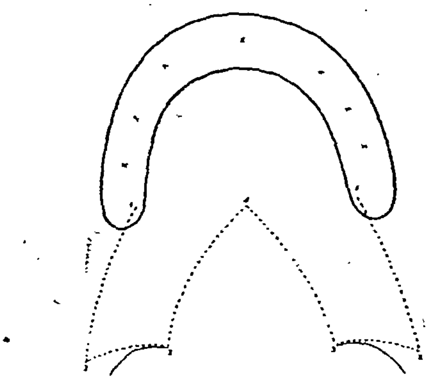


The reflected and pivoting flaps of Fig. 16 shown in position.

At a later period the posterior portion of the cleft may be closed in various ways, the method varying with the breadth of the cleft and the extent of material at disposal. The first and more generally applicable method is by reflecting a flap inwards on one side, leaving it attached by its inner margin, the other flap being rendered raw on its posterior surface and its area extended, as in Figs. 7 and 8. The second method is to reflect a flap inwards as before, while the flap from the opposite side is raised from the subjacent parts by an incision extending along its inner, posterior, and outer margins, so that it pivots anteriorly and can be made to cover the flap reflected from the opposite side. Or both flaps may be made, as in Fig. 18, to pivot upon their anterior attachments; their internal edges are sutured carefully together, the outer free margins being anchored wherever a suitable attachment can be found. The free inner margins of the cleft are also pinned down to the superjacent flaps by sutures.

In Fig 18 the dotted outline 1, 2, 3, 4 represents the form of the flap cut from the under surface of the palate. This pivots upon its attachment 1, 4.

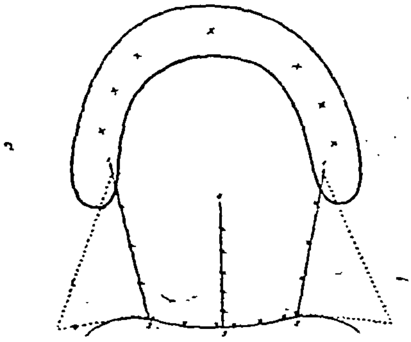
FIG. 18.



Mode of employment of pivoting flaps to close gap left in Fig. 17.

In Fig. 19 these pivoting flaps are shown in apposition along the line 4, 5, where their edges are united to one another. Their outer margins are united to the exposed surface of the soft palate along the line 1, 2.

FIG. 19.



Pivoting flaps outlined in Fig. 18 shown in position.

Cavendish square, W.

THE SANITARY INSPECTORS EXAMINATION BOARD.—An examination for certificates of qualification for appointment of sanitary inspector or inspector of nuisances under Section 108 (2) (d) of the Public Health (London) Act, 1891, will be held at the Examination Hall, Victoria Embankment, London, on Tuesday, Jan. 14th, and the four following days. Particulars will be forwarded on application to the honorary secretary, the Sanitary Inspectors Examination Board, 1, Adelaide Buildings, London Bridge, London, E.C.

A PRELIMINARY NOTE ON THE KINEMATOGRAPH IN MEDICINE.

BY H. CAMPBELL THOMSON, M.D. LOND., F.R.C.P. LOND.,

PHYSICIAN TO OUT-PATIENTS AT THE MIDDLESEX HOSPITAL; PHYSICIAN TO THE HOSPITAL FOR EPILEPSY AND PARALYSIS, MAIDA VALE.

THE results which I have obtained with the kinematograph as an aid in the teaching of nervous diseases, and which I have been able to demonstrate at the Middlesex Hospital and elsewhere, have met with such expressions of encouragement from my colleagues and other members of the medical profession as to lead me to think that it may be of some interest to publish a few notes on the uses and possibilities which this method of demonstration appears to offer. In connexion with the teaching of medicine diseases of the nervous system are especially well adapted for bioscopic illustration, since the abnormalities of movement can be all faithfully reproduced.

The illustrations accompanying this article are enlarged from isolated examples taken from a section of films and they depict the momentary attitudes of the patients as photographs were being taken of them at the rate of 16 a second. For the care and trouble taken in producing these films I have to thank Mr. Charles Urban. From the appearance of these enlargements some idea may be gathered of the sharpness of definition which is obtained in the original films. These are all pictures of abnormal movements of pronounced character and will form the basis of the demonstration which, at the invitation of the council, I hope to give before the Medical Section of the Royal Society of Medicine at the end of January.

The first figure illustrated is that of a man with ataxy of the limbs who is depicted in this photograph as he is in the act of turning and the position of the left leg, in which the trouble is the more pronounced, gives some idea of the type of gait which can be so well seen in the moving pictures, as likewise can the incoördination of the arms, and the tendency to fall backwards, to which he is also subject.

The next two figures are illustrations from a case of disseminated sclerosis. The ataxic-paraplegic walk and the attempts to preserve the balance by the movements of the arms are well shown; in the second picture the patient has been photographed while in the act of drinking in order to bring out the "volitional" tremors. His efforts to raise the glass to his lips, accompanied as they are by tremors of increasing amplitude and spilling of the water, make up a picture which cannot fail to impress itself on all who see it. From this case films have also been taken to show nystagmus and the rapid oscillations of the eyes as they are turned to one side or the other can be clearly seen and, moreover, can be contrasted with an example of slow nystagmus which has been obtained from a case of Friedreich's disease.

In the fourth figure we have an example of a paraplegic gait resulting from a myelitis.

The fifth picture is taken from a case of pseudo-hypertrophic paralysis in which the characteristic waddling method of progression is shown, and here the instantaneous photograph has depicted the patient's right leg in the position of "high-stepping" gait which is so apt to be assumed by patients with such muscular weakness as makes it difficult for them to clear their feet from the ground. Bioscopic illustrations have also been obtained of the method by which this patient gets up from the ground by "climbing up his legs."

The sixth figure is taken from a case of cerebral diplegia with athetosis. The continual squirming, involuntary movements which affect the head and face as well as the hand, are realistically shown and films have also been obtained of the patient walking.

The seventh figure illustrates the posture of a case of paralysis agitans, and by means of the bioscope the characteristic tremor of the hands can be seen. The typical "mask"-like face can be easily identified by a series of pictures which show the rigidity of the countenance being maintained while the patient is talking, and this has been made still clearer by comparison with the facial expression of another case in which tremor has arisen from a different cause.

The last picture shows the act of testing the knee-jerks.

Enough has been said to give a general outline of some of the movements which have been already photographed for demonstration, but it is, of course, possible to record all the main diagnostic points of a case, as in one instance has been done. The absence of signs can also be recorded as well as their presence and the presence or absence of anæsthesia can be demonstrated by asking the patient to raise his hand or to make other signs indicating his abilities to feel or not as the case may be. To begin with, one has naturally chosen cases where the movements have been of an exaggerated nature, but the fact that nystagmus can be shown is a clear indication of what can be done with movements which are less pronounced. Indeed, given a suitable light, it is possible to take the finest movements and I hope shortly to be able to demonstrate this by showing the movements which occur during the electrical reactions of muscles.

No doubt ideas will occur to readers in which a record of many medical cases other than those of nervous diseases will be useful, for the whole aspect of a case is often different according to whether it can be seen in lifelike movements or only in stationary illustrations. The practice of surgery would also seem to offer great facilities for demonstration by kinematograph, but hitherto, so far as I am aware, little or no serious work has been undertaken for purposes of teaching. It is true that a French surgeon has had bioscopic pictures taken of some of his operations, and extremely interesting as these pictures are in depicting technique and in demonstrating the possibilities which are thus opened up they cannot be regarded as being of serious use for systematic instruction. For the purpose of instruction it is necessary that the great principles should be illustrated and for this purpose it will almost certainly be best to take photographs from the cadaver where the desirable positions and lights can all be arranged at leisure. Operations on the eye would probably afford excellent examples for teaching purposes, as also would the manipulations of dislocations and fractures. Needless to say it is neither necessary nor desirable that the identity of the operator should be brought into the pictures. Only his hands need be taken and, indeed, apart from obvious ethical reasons, to do otherwise would to a large extent decrease the value of the photograph by obtaining an extended field at the expense of a loss of detail.

Photographs of moving micro-organisms must be ranked among the most striking results that have hitherto been obtained with the kinematograph. The movements of the various bacilli—e.g., those of typhoid fever—can be shown on the screen and should be of value in the teaching of hygiene and bacteriology. The teaching of physiology should also benefit by this method, inasmuch as various physiological experiments which it is frequently impossible to repeat before a class could be demonstrated as often as required.

For the general purposes of class teaching in medical and other forms of education there can be no doubt that the kinematograph will prove to be very useful and its management is but little more trouble than that of the ordinary lantern. Moreover, with the most modern types of machine it will be possible to stop at any one picture and thus to combine with the kinematograph all the advantages of an ordinary lantern without any danger of firing the films.

It may be taken, however, that we are as yet only at the beginning, so to speak, of this method of observing pictures of moving life, and, indeed, I am given to understand that at the present time a small hand machine in which the movements will be obtained by a simple clockwork motor and for the illumination of which the reflected light of an ordinary electric lamp, candle, or daylight will be sufficient, is in course of construction. Such a contrivance will form an important addition to the equipment of the practitioner who is unable to keep in touch with the larger centres of education, for in addition to his reading he will be able to study many of his cases as they appear in life, and to the student there will be given another valuable method of revising and summarising his knowledge.

DIABETES MELLITUS IN TWO BROTHERS, WITH NECROPSIES.

BY W. CECIL BOSANQUET, M.A., M.D. OXON.,
F.R.C.P LOND.,
ASSISTANT PHYSICIAN TO CHARING CROSS HOSPITAL, LONDON, W.C.,
AND TO THE HOSPITAL FOR CONSUMPTION AND DISEASES
OF THE CHEST, BROMPTON.

THE following cases of diabetes appear to possess some points of interest which may render them worthy of record. The first patient came under my care on the occasion of his first stay in hospital, after the most acute period of his attack was past, the credit for the successful treatment being due to Dr. F. W. Mott, whom I have to thank for permission to publish these notes.

CASE 1.—The patient, a boy, aged 14 years, was admitted to Charing Cross Hospital on May 16th, 1905, complaining of increased hunger and thirst, of loss of flesh, of the passage of large quantities of urine, and of pain in the abdomen. All these symptoms were of five weeks' duration and had apparently arisen almost suddenly. For the last three weeks the lad had noticed that his sight was bad and he had stayed away from school in consequence. His past history had been uneventful, but he had suffered from alopecia areata for the past five years and at the time of admission exhibited extensive areas of baldness chiefly affecting the right side of the scalp. His mother and a cousin had died from diabetes, and both of these relatives had been affected with alopecia in the same region as the present patient.

On examination the patient was found to be a somewhat emaciated youth, with a flushed face and somewhat dirty tongue. The lower border of the liver was palpable just below the costal margin; no knee-jerks or plantar reflexes could be obtained. His mental condition was dull and drowsy but he answered questions intelligibly when roused. During the first 24 hours—being on an ordinary diet—he passed 56 ounces of urine containing 9·1 per cent. of sugar (nearly 153 grammes). No acetone or diacetic acid was detected by the ordinary tests. On the 17th he was ordered a strict anti-diabetic diet with the exception of a daily allowance of two pints of milk, He was also given 25 minims of solution of morphine three times a day. The quantity of sugar in the urine increased instead of diminishing. On the 19th he passed 374 grammes of sugar; the drowsy condition had deepened and acetone and diacetic acid were now present in the urine in considerable amounts. On the 20th and 21st he was practically comatose but could just be roused to take nourishment; no symptoms of "air hunger" were noticeable. On each of the last-mentioned days he was given an enema of saline solution containing one drachm of bicarbonate of sodium and on the 23rd the dose of solution of morphine was increased to 40 minims thrice daily. The lad's mental condition gradually improved and the quantity of sugar passed decreased concurrently. Some slight recurrence of the drowsiness was observed between July 3rd and 6th, but it did not become deep. Acetone and diacetic acid were detected daily in the urine up to June 14th and a trace of one or other was found on a few subsequent occasions. On the whole, fairly steady improvement took place. On the 16th it was discovered that by a mistake on the part of the nursing staff the patient had been receiving a daily "portion" of milk pudding (rice, tapioca, sago). This was ordered to be discontinued. The subsequent history of the case while in hospital was uneventful. The reduction in diet was not immediately followed by any marked diminution in the amount of sugar excreted in the urine but gradually the quantity of urine fell, the percentage of sugar remaining at first pretty constantly about 4 per cent. The dose of morphine taken was reduced on July 1st to 25 minims and on August 8th to 15 minims thrice daily. The boy left the hospital much improved on August 19th.

The patient was readmitted on Jan. 9th, 1906. His weight was then 6 stones 4½ pounds. For the first month of his stay in hospital, during which he was placed on a strict anti-diabetic diet with the exception of the same allowance of milk as before, he passed on an average 266 grammes of sugar per diem. On Feb. 23rd he was ordered one ounce daily of acid extract of duodenum (secretin) kindly supplied by Professor E. H Starling. The amount of sugar excreted appeared quite uninfluenced by the remedy; the acetone and diacetic acid present in the urine seemed to increase slightly but they were not quantitatively estimated. The secretin was discontinued on March 1st. On the 7th the patient was given a daily portion of tapioca pudding; again there seemed to be some increase in the amount of acetone bodies excreted in the urine but the amount of sugar did not rise, the average at this period being approximately 200 grammes daily. Gradual diminution in the quantity of urine was recorded after this date. On April 11th the boy was allowed four ounces of potatoes daily but still no increase in sugar-excretion occurred. He left the hospital, improved in general condition, on April 18th. Subsequently he attended at intervals in the out patient department, remaining apparently in much the same state. At the beginning of November, however, he got rapidly worse and was readmitted on the 27th of that month—his first appearance at the hospital for some weeks. He was now very drowsy and was roused with difficulty. The urine contained 2·5 per cent. of sugar and much acetone and diacetic acid. His weight was 5 stones 2¼ pounds. His temperature rose to 102·4° F. and he died comatose on the second day after admission.

At the necropsy no apparent cause for the fever was discovered. The pancreas was extremely atrophic, weighing only one ounce. Microscopically it exhibited slight fibrosis and some fatty change; the islands of Langerhans appeared normal. The kidneys were large, weighing seven ounces each, and on microscopical examination they showed parenchymatous nephritis.

CASE 2.—The patient, a youth aged 20 years, was admitted to hospital on Dec. 17th, 1905. His illness had begun gradually five years before with thirst as the prominent symptom. Three months before admission the thirst had increased and the patient became weak. His vision grew indistinct and his gums became sore and swollen.

On admission the patient appeared to be weak and listless. He had a small carbuncle on the right cheek, and Mr. E Treacher Collins found commencing cataract in both eyes. The urine contained a considerable quantity of sugar, reaching 340 grammes in the first 24 hours and 470 grammes on the second day. He suffered from what he called "diarrhœa," the frequent passage of large formed motions. On the 20th he was strictly dieted, with the exception of an allowance of two pints of milk. After this the average amount of sugar passed in 24 hours was about 160 grammes. From Jan. 9th to 12th, 1906, he was drowsy; his skin was moist and the "diarrhœa" continued. On the 23rd he was put on secretin, two ounces of the acid extract of duodenum supplied by Professor Starling being given daily. This was continued till Feb. 11th. The amount of sugar passed during this period was on an average 170 grammes. Acetone bodies, which had appeared previously, increased in amount, and the diarrhœa became more troublesome. The motions contained some undigested muscle fibres and 12½ per cent. of fat. On Feb. 7th he surreptitiously ate a currant bun and true diarrhœa with liquid stools supervened. The patient became obviously more ill and drowsy. On discontinuing the secretin gradual improvement occurred—subjective at first, but afterwards objectively apparent. From the 11th to March 2nd the average daily amount of sugar secreted was approximately 124 grammes; the acetone bodies varied in quantity from time to time. On March 8th he was again worse, being more drowsy and having more diarrhœa. He was given strychnine, brandy, and doses of sodium bicarbonate. During the 12th and 13th he was put upon a milk diet alone. In spite of everything the diarrhœa continued to be troublesome and the patient appeared to be getting weaker. On April 4th a change of diet was tried, four ounces of potato being added to the daily portion. The sugar in the urine rose somewhat, averaging during the first week 171 grammes daily. The patient seemed in spite of this to gain strength; the diarrhœa was no worse. On the 11th he was given in addition to the potato a portion of milk-pudding and again the sugar rose slightly, reaching 180 grammes, but the general improvement continued. On the 23rd a final addition of four ounces of bread was made. The sugar rose no further but tended rather to fall in amount, the subsequent average being 136 grammes up to May 7th, the last estimation made. He was discharged to the convalescent home on May 30th still suffering from slight diarrhœa but stronger than he had been for some time. At the end of a week at the home the diarrhœa became so severe as to render it advisable for him to return to hospital.

The patient was readmitted on June 9th, 1906. The diarrhœa was troublesome and there was some œdema of the ankles. The pulse was weak and frequent and the patient seemed ill and exhausted. His weight was now 6 stones 1¼ pounds. He was again dieted and was treated with enemata of starch and opium for the first few days, receiving later a mixture containing salicylate of bismuth. The diarrhœa gradually lessened in severity but remained to some extent throughout his stay in hospital. At one period he developed a small carbuncle in the left external auditory meatus and the parotid lymphatic glands became swollen; this condition subsided satisfactorily. The record of the daily excretion of sugar at this period is unfortunately so imperfect as to render it impossible to draw any valid inferences therefrom. The patient gradually gained weight, reaching 6 stones 5 pounds, and went home on August 22nd at his own desire. He came up as an out-patient on Sept. 7th and again on the 14th. On the latter occasion he looked weak and ill but professed to be as usual and declined admission. In the following week, however, he was much worse and seemed scarcely able to walk. He complained of nothing but the diarrhœa and would not admit that he suffered from thirst, polyuria, cough, or any other trouble. He was readmitted rather against his inclination, it being obviously dangerous to allow him to leave the hospital. On admission he became much collapsed, the pulse being scarcely perceptible. The urine contained a large percentage of sugar but no acetone or diacetic acid. He rallied a little under the influence of stimulants. His temperature rose to 103 8° F. Signs of consolidation of the upper lobe of the right lung were discovered, incontinence of urine and fæces ensued, and he died on the next day from exhaustion without any sign of coma.

At the necropsy the upper lobe of the right lung was found to be covered with a layer of fibrinous exudation. The lung itself was the seat of caseous pneumonia. The duodenum and upper part of the jejunum were thickened throughout and the mucous membrane was covered with a layer of mucoid material. Microscopically the mucosa was infiltrated with leucocytes and the epithelium exhibited an undue number of goblet cells; the peritoneal coat was slightly thickened. There was pigmentation from chronic congestion in the region of the cæcum and here and there throughout the colon. The kidneys showed some cloudy swelling but were otherwise normal. The liver was somewhat fatty. The pancreas was much reduced in size, weighing only 1¼ ounces (37 grammes). The secreting substance was especially diminished in amount, there being a considerable quantity of fibrous tissue around the duct of Wirsung which helped to make up the small weight actually recorded. There was no fibrosis of the gland, although the arteries were much degenerated (arterio-sclerosis). The islands of Langerhans were visible in fair numbers and appeared normal in structure.

Comments.—1. The hereditary incidence of diabetes is well illustrated in the cases recorded, no less than four members of one family being affected. The coincidence of alopecia areata in three of them is remarkable.

2. In Case 1 the rapid onset of the disease is noteworthy, as is also the abdominal pain by which its appearance was accompanied. The occurrence of some acute affection of the pancreas is suggested. In the other brother the disease had lasted for five years and had begun more insidiously. No exciting cause was traceable in either instance.

3. In Case 1 the recovery from so deep a condition of coma was remarkable. The lad subsequently died comatose and the kidneys showed acute inflammation. The association of coma in diabetes with renal defect is worthy of careful investigation, as the rapid accumulation of the poisons at work is most easily explained by the occurrence of some failure in the excretory apparatus. In a recent case of fatal coma occurring in Charing Cross Hospital there was found suppurative nephritis, and in my own experience it is usual to find signs of renal mischief in such cases. The relation of coma to acetonæmia is illustrated in these cases, the second patient who died from pulmonary disease without coma not exhibiting these bodies in the urine at the end. It was noteworthy, however, that Case 1 on first admission was drowsy but exhibited no acetonuria. The dependence of acetonæmia on lack of carbohydrate food was not apparent, the first boy passing into coma and out again while taking a daily portion of milk pudding, and some increase in the amount of the acetone bodies excreted being noted on one occasion (March 7th) immediately after an increase in the allowance of starchy food.

4. In Case 1 the amount of sugar in the urine varied independently of the diet taken. It rose notably as a sequel to putting the boy on a stricter diet—he had been taking ordinary food previously to admission. The subsequent omission of the unauthorised milk pudding did not cause an immediate fall in the excretion of sugar, nor on a subsequent occasion did an addition to the allowance of carbohydrate increase it. In the second case the lad seemed to improve considerably when allowed an additional amount of carbohydrate, in spite of the slight increase of sugar excreted in the urine. The phenomena observed in these two cases seem to me to be in favour of the explanation of the origin of sugar in diabetes which I set out in my Goulstonian lectures in 1905—viz., that some portion of the sugar arises from a breaking-down of the cells of the body, in addition to that which may be due to some defect in the process of absorption of sugar from the alimentary canal or of its destruction in the body. If this be the case a parallel may be drawn between the formation of sugar and that of uric acid, part of each being exogenous, part endogenous.

5. The failure of secretin to act beneficially in either of these patients was disappointing. Since, however, the action of secretin as recognised by its discoverers is to increase the flow of pancreatic (digestive) juice, its employment in diabetes can only be upheld on the principle that the formation of the internal secretion of the pancreas and that of the digestive ferments take place as a single chemical action, the living substance breaking down simultaneously into both these substances. Now if, as I previously suggested, the action of the pancreas lies in neutralising some poison formed elsewhere in the body—such neutralising action consisting perhaps in making use of the substance in question for its own metabolism—the absorption of secretin will not directly affect the relation of the gland to the formation of sugar.

6. The anatomical condition of the pancreas in these two cases was striking; in each there was marked atrophy of the organ without noteworthy alteration of structure, the fibrosis in the second case being comparatively slight. In each case there were plenty of normal-looking islands of Langerhans. It is therefore difficult here to associate diabetes with structural lesions of these islands. The cases tend to support the view of Hansemann that the typical condition of the pancreas in diabetes is atrophy, affecting the secreting cells as a whole. In each of these cases there was well-marked arterio-sclerosis, which is in my experience the most constant feature in the pancreas in cases of diabetes, having been present in every one of eight cases which I have examined in the last two years. The hyaline change met with in the islands in some instances appears to be most often of the nature of an arterio capillary fibrosis; in other cases hyaline blood-clots and degenerate cells may present a homogeneous appearance.

7. The condition of the small intestine in the second case is noteworthy. It was clearly associated with the diarrhœa which was so troublesome during life How far the diminished assimilation of fat and of muscle-fibre was due to the intestinal disease and how far to the pancreatic defect cannot be determined. The fact that some fibrosis of the pancreas occurred in the first case and not in the patient who suffered from duodenal catarrh suggests that this lesion was dependent upon the arterial condition and was not inflammatory.

Harley-street, W.

A CASE OF "DIPHTHERIA OF THE SKIN" OF THREE YEARS' DURATION TREATED BY ANTITOXIN.

BY ALAN B. SLATER, M.D. EDIN.,
PHYSICIAN TO THE SKIN DEPARTMENT, FARRINGDON GENERAL DISPENSARY.

A GIRL, aged 13 years, came under my charge on June 20th, 1907, with the following history. Three years previously she was taken to an eye hospital for inflammation of the eyes. She was treated there at the time but the medical officer at the hospital told the mother that the child was very ill and that she ought to have a medical man to attend her at home. The child, however, improved at home and no medical practitioner was sent for. A week or two later, the exact time is not known, the mother noticed when washing the child's clothes that her linen was stained and on examining the child herself she found two white patches, one on the inside of each labium, and also a thin discharge. This was treated by the mother by bathing with water. Shortly after this blisters began to develop round the vulva and spread on to the abdomen. The child was then taken to a general hospital and was admitted, the vesicles having spread so rapidly that she was practically covered by them about the body and neck, and there were a few on the face and head. She remained in the hospital about five months and during that time made little or no progress, the only change being that the abdomen cleared and the vesicles were confined to the parts round the vulva, the chest, the neck, and the head (including all the face). Since then she has been treated for syphilis, a section taken of one of the vesicles showing some appearance of syphilis.

Mercury and iodides were given for about two years without much effect, but the child's general condition improved and the vesicles still were confined to the vulva, the chest, the neck, and the head, the face being especially affected. Lotions of almost every kind were used without having any effect. Some idea of the amount of discharge from the whole surface of the skin, due to the vesicles rupturing, may be obtained from the fact that during the whole time since she left the hospital her mother has had to change all her clothes, always twice, and as many as four times a day, in addition to wrapping all the affected parts in linen or cotton.

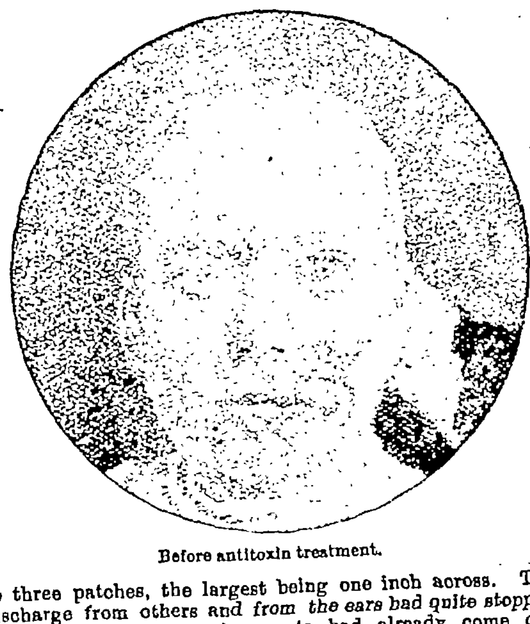
On June 20th the child's appearance and condition were as follows. There were masses of vesicles round the left side of the mouth extending to the cheek, but not into the mouth; others on both eyebrows, the right being worse than the left. The external meatus of both ears was filled with thick semi-purulent discharge, the lobes of the ears and behind the ears being covered with discharging vesicles. Upon the head were large masses of vesicles and some dried scabs where former ones had been. The neck and shoulders had large quantities of vesicles on them extending down to the nipples on either side and as far as the middle of the scapulæ on either side at the back. In the areas affected the space between the vesicles was dark red, but in other areas which had been affected and where the vesicles had disappeared the skin was only slightly erythematous or even normal, no scarring being left behind. The region of the vulva was erythematous and studded with vesicles, but this condition did not go back further than the vulva itself; the whole affected area thereabouts extended to three or four inches down the inner part of the thighs and about four inches up the abdominal wall. All the areas were discharging freely, a thin clear fluid dripping from the chin at the rate of a drop per minute. In many places the vesicles were arranged in crescentic form as though the discharge had run over the surface of the skin and infected it as it went along. The general condition of the child was good; she was well nourished and felt quite well in herself and also ate well. There was no sign of any constitutional disturbance, the spleen was not enlarged, the heart was normal, and the urine was free from albumin. From the following bacteriological investigation I decided to treat her by means of diphtheria antitoxin.

Bacteriological report by DR. J. G. HARE.—On June 30th made a bacteriological examination of the serous fluid which was dripping from the face. Smears were made from the fluid and stained with methylene blue and by Gram's method. In these were observed organisms resembling the diphtheria bacillus. I inoculated an agar tube and also a blood serum tube with the fluid and incubated them at 37° C. A growth appeared on the media 18 hours later. These were then plated and the staphylococcus aureus and albus were isolated, together with a bacillus which formed small cream-coloured colonies on agar. On smears being made from these colonies and stained with Löffler's methylene blue and examined a bacillus was observed closely resembling the bacillus of diphtheria. The organism also reacted to Neisser's stain. (In inoculating the tubes the needle was never allowed to touch the skin, the fluid being merely allowed to drip on to the needle.) The organism was obtained in pure culture on blood serum and when stained and examined showed the characteristic involution (club-shaped) forms. Subcultures were then made on gelatin, on potato, in milk and in broth. On gelatin the growth was slow and without liquefaction. In broth there was a whitish granular deposit at the bottom of the tube, the broth otherwise remaining clear. On potato a faint, almost invisible, growth was seen. Milk was not coagulated. Gas was not generated in any of the media. The indol reaction was obtained by the addition of a nitrite.

Through the courtesy of Professor R. T. Hewlett animal inoculations were carried out at King's College. A 300 gramme guinea-pig was inoculated per peritoneum with two cubic centimetres of serum-suspension of this culture and at the same time another guinea-pig was inoculated with the same quantity of culture + 1·5 cubic centimetres of diphtheria antitoxin. The first guinea-pig died in ten days; the second developed no symptoms. The post-mortem appearance of the first guinea-pig showed extensive œdema of the peritoneum, hæmorrhages, and enlargement of the spleen. Cultivations were obtained from the heart and peritoneal fluid and showed the Klebs-Löffler bacillus in pure culture.

Antitoxin treatment.—This was begun on July 2nd. 2000 units of Burroughs and Wellcome's ordinary anti-diphtheritic serum were injected into the subcutaneous tissue of the abdomen at 3 P.M. At 10 P.M. there was some œdema at the seat of injection together with an erythematous rash all over the body and limbs and also discomfort from thirst. There was vomiting at intervals of an hour until 8 A.M. when it stopped and the child had a good sleep. By 1 P.M. on the 3rd the rash had disappeared and the patient was quite comfortable. By this time there was a marked change in the appearance of the vesicles, which had not only ceased to discharge but were in many places quite dry and beginning to form a crust, the change being remarkable. The temperature remained at 99 8° F. On the 4th constitutional symptoms were still absent and at 1 P.M. 1000 units were injected. At 6 P.M. no rash or other result of antitoxin was present but two of the areas became active again and discharged during the evening. The temperature was 99·8°. On the 5th 2000 units were injected. No constitutional symptoms were observed during the day. The affected areas were reduced to three patches, the largest being one inch across. The discharge from others and from the ears had quite stopped and in many places the crusts had already come off, leaving healed skin. The diet was exclusively milk. The temperature was 99·6°. On the 6th no symptoms were noticed until the evening after an egg and bread-and-butter had been eaten, when a slight erythematous rash appeared on the legs and abdomen. The patient was well in herself and hungry. The temperature was 99 6°. The vesicles were about the same. On the 7th there was a fine papular rash over the abdomen and thighs but no other symptoms. The vesicles were still discharging a little but no more had appeared and large areas on the shoulders and neck and head were quite free, only erythematous skin remaining. The vesicles were confined now to an area one inch across on the right side of the mouth, one similar on the left eyebrow, and two smaller ones on the front of the scalp. The vulva was quite free from vesicles but was still erythematous. The temperature was 99·4°. On the 8th the rash had all disappeared and the child was quite well in herself. The bullæ were painted with a

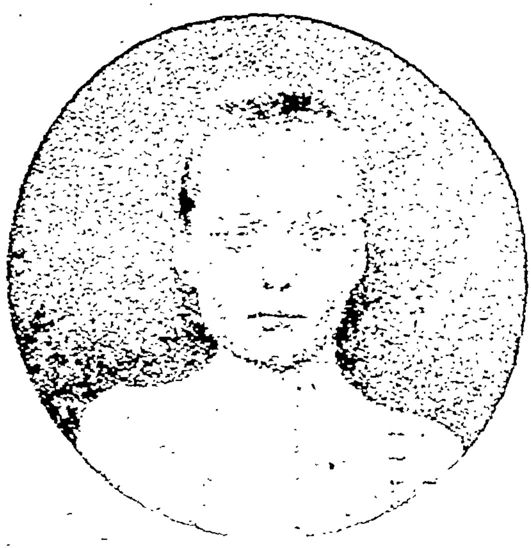
FIG. 1.



Before antitoxin treatment.

mixture of carbolic acid and glycerine. The temperature was 99·4°. On the 9th the vesicles were discharging more and an affected area behind the right ear measuring three quarters of an inch across had appeared. 2000 units were injected. The temperature was 99·2°. On the 10th there was no constitutional disturbance from the last injection. With the exception of that behind the ear all the others were drier and smaller in extent. The neck, the shoulders, and all the back of the head were free from even crusts. The vulva was free from vesicles also. The affected areas were painted with carbolic acid 1 to absolute alcohol 20 and afterwards dusted with boric acid powder. The temperature was 99°. On the 11th 2000 units were injected. All the vesicles were much drier, including the ear. The temperature was normal and the painting was continued. On the 12th no constitutional symptoms were observed. The vesicles were reduced to areas of a quarter of an inch behind the ear, one over the left eyebrow, and one of half an inch on the right side of the mouth. Painting was continued. The condition on the 13th was the same as on the previous day. On the 14th one vesicle reappeared on the front of the scalp and one on the left cheek; others were the same in extent but were discharging a little more. *Other* areas had kept entirely free and in many places the skin was normal; there was no scarring. The temperature was normal. On the 15th 2000 units were injected. Withholding the antitoxin evidently allowed the disease to become active again, as single vesicles appeared in two new places on the face and the *other ones* were discharging more. On the 16th the discharge was less again, the single vesicles were dried up, and other areas were much drier; only three areas were discharging. On the 17th 2000 units were injected. There were no constitutional symptoms and every area was drier. The temperature was normal and painting was continued. On the 18th the patient was quite well generally. The affected areas were still smaller and there was very little discharge. The temperature was normal. On the 19th 2000 units were injected into the thigh. All the areas were frequently bathed with 1 in 20 carbolic lotion, then painted with 1 in 20 carbolic in absolute alcohol, and dusted with boric powder. A culture was taken from the only discharging spot. On the 20th the injection had caused the thigh to swell to almost twice the size and there had been great pain all night. The glands in the groin did not enlarge. The temperature rose to 101°. All discharge had completely stopped and a few crusts only remained. The tube inoculated on the previous day showed no growth of any kind after 24 hours' incubation. On the 21st the swelling of the thigh had disappeared. There was slight swelling over the seat of the injection. The condition had greatly improved and the temperature was normal. On the 22nd the improvement was maintained.

FIG. 2.



After 7000 units had been injected. Showing erythema left behind.

Remarks.—There seems to be no doubt that the most important factor in this case was the Klebs-Löffler bacillus. The disease apparently commenced as an acute attack of diphtheria, the primary seat of infection being the eyes. From this focus the vulva became infected and then the bacteria in some way found their way into the superficial lymphatic circulation, producing a condition resembling herpes, probably as the result of peripheral neuritis set up by the bacilli themselves. This theory is based on the fact that during the whole of the duration of the disease, since the primary acute symptoms, the lesions have been confined to the superficial layers of the skin (proved by the fact that no scarring was left). Whether the staphylococci played any important part is difficult to say, but they probably had only a mild influence, if any at all, as the use of various lotions, such as 1 in 40 carbolic lotion, and perchloride of mercury 1 in 1500 had no effect on the lesions, whereas the effect of the antitoxin was remarkable.

Bryanston-street, W.

AN UNUSUAL PATHOLOGICAL CONDITION OF MECKEL'S DIVERTICULUM.

BY C. H. TURNER, M.R.C.S. ENG., L.R.C.P. LOND.,
CAPTAIN, R.A.M.C.

THE patient, aged 23 years, was admitted to the Station Hospital, Rawal Pindi, on Jan. 4th, 1907. As history it was stated that on the morning of the 3rd, on getting up, he was seized with violent pain in the abdomen, chiefly the lower part, and vomited. He was admitted to the Cavalry Hospital and treated by enemata and fomentations to the abdomen; these were effectual in opening the bowels, which had been constipated, and in relieving the pain considerably. He was transferred on the following morning to the Station Hospital.

On admission the patient's general appearance was good, both as regards colour and facial expression; his tongue was furred but moist at the edges. The temperature was normal and the pulse was 100. He gave an intelligent account of the onset of his illness and complained at the present time of pain in the iliac fossa on the right side, radiating towards the umbilicus. He had vomited once during the night and had not had the bowels open or passed flatus since having the enemata the night before. On examining the abdomen there was seen to be slight distension, and movement on respiration was impaired. There was slight general tenderness over the abdomen, but more marked in the right lower quadrant; resistance here, too, was marked. No tumour could be made out. The percussion note was hyper-resonant over all the abdomen, with the exception of the right flank where the note was dull. A diagnosis of acute appendicitis with fairly extensive localised peritonitis was made and it was decided to operate if the pulse-rate had not dropped by the morning. The patient passed a restless night and the temperature, which had been normal on admission, was 101° F. and the pulse was 112; he had vomited slightly twice during the night; the physical signs were the same, the pain if anything being more severe.

Operation.—Chloroform being administered, the abdomen was prepared, as no previous satisfactory preparation had been possible owing to the tenderness. An incision four inches long was made over McBurney's point, but a little farther out, the muscles being split in the direction of their fibres. On opening the peritoneum about six ounces of turbid peritoneal fluid escaped, and distended and somewhat congested coils of small intestine presented. The cæcum could not be felt in the iliac fossa nor could any large intestine be pulled out. The incision was extended a couple of inches and the whole hand was introduced. A portion of the large intestine could then be felt quite collapsed and lying high up. This was pulled down easily and traced first in one direction where it was found to be continuous with the transverse colon; traced in the other direction it was found to take a turn upwards and forwards towards the umbilicus, and here a slight adhesion gave way and the cæcum was brought out of the wound and examined; it was also collapsed and the appendix was found to be healthy. The ileum was then followed up and the first foot was collapsed and found to be firmly adherent at this point to the anterior abdominal wall, just at the level of, and to the right of, the umbilicus. The first incision was covered up with sterilised gauze and a second incision three inches long was made through the fibres of the right rectus muscle. On incising the posterior layer of the sheath of the rectus what was apparently an abscess cavity containing four ounces of very offensive pus was opened. This was swabbed up and washed out with 1 in 40 carbolic lotion and then explored with the finger; the walls were quite smooth and felt as though formed by mucous membrane. The peritoneal cavity was opened next and carefully packed off. The abscess cavity described above was then found to be the inner surface of the fundus of a dilated and gangrenous Meckel's diverticulum, which was adherent to the anterior abdominal wall. It was then carefully separated and the coil of bowel from which it arose was drawn out of the wound. The diverticulum arose from the ileum, about 12 inches from the ileo-cæcal valve; its proximal portion was stenosed and its distal portion or fundus was gangrenous and dilated (as far as could be judged, for it had contained four ounces of pus) to the size of a Tangerine orange. The pathological condition was on a par with the "appendicitis with stenosis, empyema" classified by Mr. C. B. Lockwood. The diverticulum was removed in the same way as an appendix and the stump was tucked in, the wall of the intestine being brought together over it with Lembert's sutures. The displacement of the cæcum was due to the mesentery of the ileum being adherent to the meso-cæcum and meso-colon, and to slight adhesion of the omentum to the outer and posterior wall of the cæcum. These were separated and all bleeding points secured. A drainage-tube was placed in the whole length of the wound in the middle line and brought out at its lower extremity, and the abdominal walls were brought together over it with one layer of sutures, a separate layer for the peritoneum not being practicable owing to its friability. The wound in the iliac region was closed in separate layers.

The after history of the case was as follows. The patient did not suffer from shock, though the operation lasted about one and a quarter hours. His condition gave rise to some anxiety for the first 36 hours, owing to the difficulty of overcoming the paralytic distension of the bowel, but this was effected by calomel and enemata, and the second day after the operation the bowels opened naturally and the hiccough, which had been rather persistent, stopped and the pulse-rate dropped from 120 to 98. Convalescence was uninterrupted and the wound in the iliac region healed by first intention. There was a fair amount of discharge from the tube in the other wound, but at the end of a week this had stopped and the wound soundly healed in 14 days.

Remarks.—Cases of Meckel's diverticulum are sufficiently uncommon to warrant their publication, and the above case is one of unusual interest from a pathological point of view. Cases in which the diverticulum has caused acute obstruction by strangulating the bowel have been frequently reported, but I have not the literature at my disposal to look up the subject. I should be glad to hear if any cases of a similar nature have come under the notice of any readers of THE LANCET.

Rawal Pindi, Punjab, India.

DELIRIUM TREMENS (MANIA E POTU):

STATISTICAL STUDY OF 156 CASES.[1]

BY L. NAPOLEON BOSTON, A.M., M.D.,
ADJUNCT PROFESSOR OF MEDICINE AT THE MEDICO-CHIRURGICAL COLLEGE; PHYSICIAN TO THE PHILADELPHIA HOSPITAL; AND DIRECTOR OF LABORATORIES FOR CLINICAL RESEARCH AT THE AMERICAN HOSPITAL FOR DISEASES OF THE STOMACH.

I HAVE made a statistical analysis of the hospital records for 156 cases of delirium tremens treated at the Philadelphia Hospital (*Blockley*) between Jan. 1st, 1904, and March 1st, 1907. In compiling statistics so as to display them in the form of tables it was found that the records of 16 of these cases were incomplete, therefore these have been omitted, and the tables include but 140 of the 156 cases treated. A number of cases that have occurred in my private practice could have been added, but it was deemed advisable to include only cases that had received hospital treatment in order that one might obtain statistics that would be of definite value. An analysis of the 140 case records showed age to be not only a predisposing factor to delirium tremens but also to exercise a decided influence upon the gravity of this condition. The number of cases observed at the different decades, the number of deaths, and percentage of mortality are set forth in Table I.

TABLE I.

Age.	Total number of cases.	Total number of deaths.	Pecentage of mortality.
20 to 30 years...	24	8	33·3
30 „ 40 „ ...	48	18	37·5
40 „ 50 „ ...	41	14	32·1
50 „ 60 „ ...	21	9	42·3
60 „ 74 „ ...	6	3	50·0

Delirium tremens is most common between the ages of 30 and 50, yet the death-rate remains almost the same during the second, third, and fourth decades. The prognosis is decidedly unfavourable in those suffering from this condition after the age of 50 years, and while the above statistics show a mortality of between 42 and 50 per cent. for such patients I am confident that a much higher death-rate is seen in private practice. Many of the cases included in Table I. had had a number of admissions to the delirium tremens wards of the hospital during the past 20 years. The greatest number of admissions for any one patient was 42, while many of the patients had had from six to 15 admissions, from each of which attacks they recovered and had been discharged from the institution as comparatively cured. These facts, though not included in any of my tables, are contradictory to the rather popular belief that those suffering from delirium tremens usually end in death during the second or third attack.

Further analysis with reference to season as a predisposing factor and its influence upon the gravity of the condition is revealed by Table II.:—

TABLE II.

Month.	Number of cases.	Number of deaths.	Percentage of mortality.
January	14	7	50·0
February	15	2	13·3
March	11	5	45·4
April	10	1	10·0
May	14	1	7·1
June	5	3	60·0
July	7	2	28·5
August	28	13	46·7
September ...	10	4	40·0
October	7	3	42·8
November ...	8	3	37·5
December... ...	11	8	72·7

It will be seen by Table II. that the largest number of cases developed during the month of August when in this climate the heat is extreme. It is further of special interest to note that August gives a death-rate of 46·7 per cent., while the average death-rate is but 37·1 per cent. Extreme cold is not without influence upon the mortality-rate, since December and January gave the correspondingly high death-rate of 72·7 and 50 per cent. respectively. During the spring months (May, April) delirium tremens is fairly common but the proportionate number of deaths is low, 7·1 and 10 per cent.

The following table (Table III.) is designed to present the various pre-existing and complicating conditions found to

TABLE III.

Pre-existing or complicating diseases.	Total number of cases.	Deaths.	Percentage of mortality.
Cases with pre-existing cardiac disease	13	11	84·6
Cases developing cardiac complications	10	8	80·0
Cases with pre-existing kidney disease	11	11	100·
Cases developing renal complications	4	4	100·0
Cases with pre-existing lung disease	11	5	50·0
Cases developing pulmonary complications	53	35	66·0

---

[1] Published through the courtesy of Dr. Joseph Neff, Director of Public Health and Charities, Philadelphia.

influence materially the mortality in 140 cases of delirium tremens studied, and of which 52 were fatal.

Twenty-two of the cases displayed more than one pre-existing or complicating condition of which ten displayed kidney and lung involvement; seven heart and lung; two kidney and heart; and three heart and stomach. Thirty-eight of the 140 cases were uncomplicated and all of these were followed by recovery. Most striking in connexion with Table III. is that all of the 15 cases showing renal complications terminated fatally. Again, great importance is to be attached to the prognostic significance of pre-existing cardiac disease which gave a mortality-rate of 84·6 per cent.; and acute cardiac complications are of but little less importance as regards the seriousness of the condition in question. Those cases developing acute pulmonary conditions (bronchitis and broncho-pneumonia) gave a death-rate of but 66 per cent.

Philadelphia.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

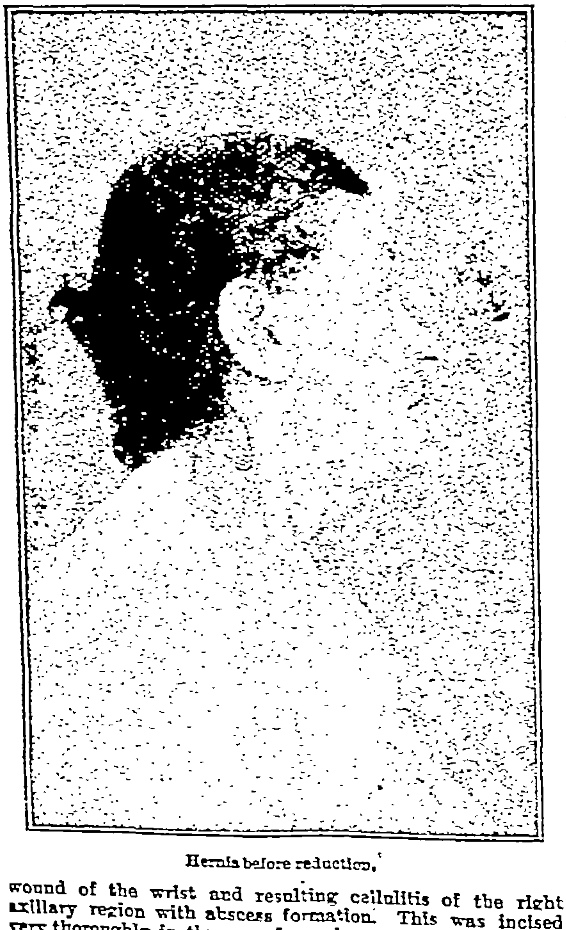
NOTE ON A CASE OF HERNIA OF THE LUNG.

By THOMAS E. COULSON, M.B., CH B. EDIN.,
LATE SENIOR HOUSE SURGEON TO THE SALFORD ROYAL HOSPITAL, MANCHESTER.

OWING to the rarity of the condition the following case seems worthy of record.

In November, 1905 a female, aged 56 years, was admitted into the Salford Union Infirmary suffering from a septic wound of the wrist and resulting cellulitis of the right axillary region with abscess formation. This was incised very thoroughly in three or four places and when she was dismissed in April, 1906, all the wounds had healed. About this time the patient noted a swelling at the lower end of the sternum but did not consult a medical man about it. On May 4th, as she was fixing her handkerchief round her neck, she suddenly discovered another swelling near the upper end of the sternum and went to the out-patient department of the Salford Royal Hospital. I saw her in the out-patient room and admitted her into the hospital under the care of Dr. A. M. Edge.

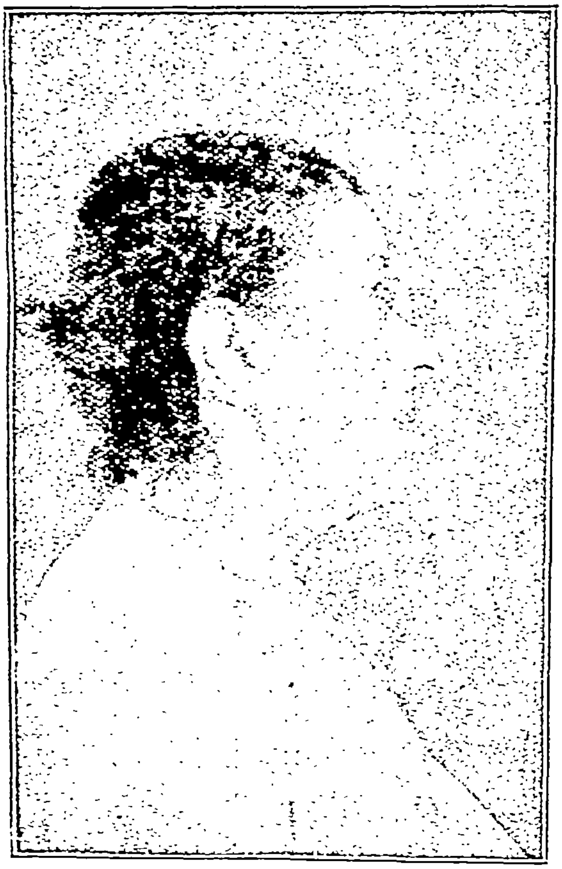
FIG. 1.



Hernia before reduction.

On admission she had two distinct and separate swellings in the region of the sternum, one at the lower end in the middle line and one at the upper end slightly to the right of the middle line. The lower swelling was about 3 inches long by 2 inches wide, tympanitic, soft, and moveable to a certain extent under the skin. There was no impulse on coughing, no breath sounds over it, and it was unaffected by taxis or pressure—evidently a collection of air in the cellular tissue. This gradually disappeared in a month's time. The upper swelling gradually increased in size and presented all the signs of pneumocele.

FIG. 2.



After reduction of hernia.

The notes at this time were as follows. On inspection it is situated over the upper end of the sternum, 5 inches in length and 3 inches in width. The outline is well-defined and smooth and tapering to a blunt point over the first right intercostal space. It moves slightly with respiration relatively to the chest wall. On palpation it is found to be soft and fluctuating. The skin moves over it and it can be moved a limited amount both up and down and side to side. Vocal fremitus is much increased over it and it has a most marked impulse on coughing which is easily visible as well as palpable. It does not pulsate. On percussion it is tympanitic to a marked degree. On auscultation there is bronchial breathing over it, low pitched, and interrupted. Vocal resonance is increased with whispering pectoriloquy. There are no adventitious sounds. When the patient speaks the swelling bulges out and becomes quite tense. There is no pain. The temperature is normal and the pulse is normal.

On manipulation the swelling can be entirely reduced within the chest by gently pressing upon the fundus and fixing the blunt neck at the first intercostal space. The swelling vanishes with a *squeaking sound quite audible both to the* patient and to the operator. The sitting posture and a few coughs bring the hernia again into prominence.

The photographs here reproduced were kindly taken for me by Dr. W. B. Anderton. The one shows the hernia before and the other after reduction.

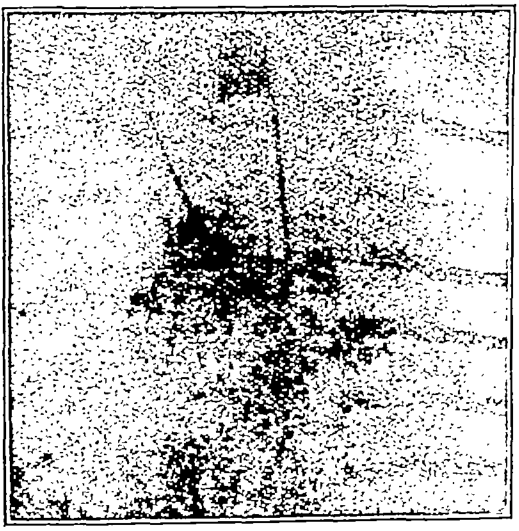
My best thanks are due to Dr. Edge for kindly allowing me to record the case.

Bristol.

OPEN SAFETY PIN IN THE ŒSOPHAGUS OF A CHILD AGED FIVE MONTHS.

BY J. S. MANSON, M.B., CH.B. EDIN.,
SENIOR HOUSE SURGEON, OLDHAM INFIRMARY.

A MALE child, aged five months, was admitted to the Oldham Infirmary on Oct. 26th, 1906, with a history of having swallowed a safety pin one hour previous to admission. A skiagram was taken and the pin was seen to lie about the middle of the œsophagus, open with the point upwards. It seemed a hopeless task to try to get the pin up by means of a probang, so it was resolved to push the pin down into the stomach and hope for the best. An ordinary stomach tube of small size was pushed down the œsophagus, and after withdrawing another skiagram was taken showing the pin lying in the stomach. The child was kept in bed and watched carefully. Milk diet was given and four days after admission a dose of castor-oil. On the afternoon of Nov. 2nd the pin was found sticking half-way out at the anus. The pin took *six and a quarter days* to accomplish the journey from the mouth to the anus and only once or twice did the child seem at all fretful.



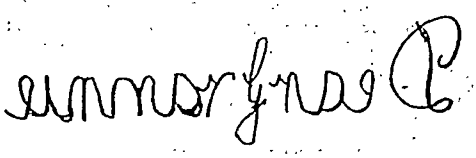
The case seems worthy of note in showing the power of the alimentary canal in dealing with a foreign body of a somewhat formidable nature. I append a *skiagram* of the pin in the œsophagus.

A CASE OF "MIRROR-WRITING."

BY VAUGHAN PENDRED, M.D. DURH, F.R.C.S. ENG.

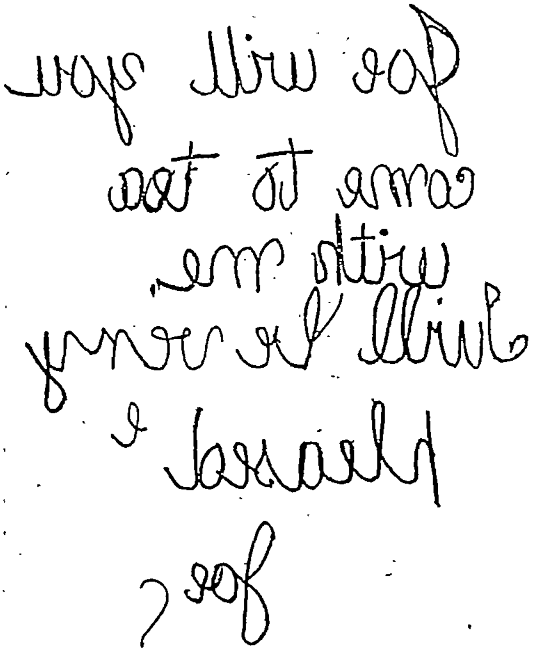
A CURIOUS condition that justly has been called "mirror-writing" has recently come under my observation. A bright, intelligent little lad, aged six years, has been learning to write for the past six months. His governess reports favourably of his application and progress, and no abnormality save the one here reported has been noted. From a copy the boy writes correctly but if left to himself to exercise his new-found accomplishment, of which he is very proud, he starts at the right hand side of the paper and writes backwards, so that to decipher the writing the paper has to be *held* up to a mirror. One day his mother suggested that he should write a letter to his grandmother. He began the letter as shown in Fig. 1 (the G is correctly formed as he copied from a letter in his mother's handwriting). He selects the "*mirror-writing*" when asked

FIG. 1.



which is correct. He reads with equal facility both the normal and the abnormal types. For example, his mother indited in "mirror-writing" the invitation contained in the three first lines of Fig. 2, to which he instantly wrote, *currente calamo*, the reply contained in the remaining lines of the same illustration. The most extraordinary confusion arises when he attempts "sums," as shown in Fig. 3. A drawing that he made of a Great Northern locomotive engine illustrates the defect in a very marked way. The engine is shown travelling to the left and is very well drawn for so youthful an artist; the letters G N.R. on the tender are in "*mirror-writing*." In writing from dictation, unless he is corrected and carefully watched, he reverses his work.

FIG. 2.



Are the pictures of letters in the boy's memory-centre incorrectly stored and therefore incorrectly reproduced? Does the receptive apparatus in the occipital lobes play this strange prank with the naturally inverted picture of letters received on the boy's retinæ? It must be noted that the letters are not inverted as would be the case if the brain merely failed to right the retinal images. I incline to the former hypothesis as it is only in the reproduction of written words that he *fails* and is quite secure in making a copy.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

THERAPEUTICAL AND PHARMACOLOGICAL SECTION.

Action of Digitalis in Cardiac Disease.—Reminiscences of an Apprentice 60 Years Ago.

A MEETING of this section was held at the Apothecaries' Hall on Dec. 17th, 1907, Dr. F. H. BURTON-BROWN, the President of the section, being in the chair.

Dr. JAMES MACKENZIE read a paper on the Action of Digitalis in Cardiac Disease. The results of animal experiments, he said, must be accepted with caution. In man the effect of digitalis was entirely dependent upon the particular lesion. If dilatation was absent, and if the tonicity of the heart was preserved, then no good resulted from the use of digitalis. If the heart was of normal size dropsy was not of cardiac origin. The irregular pulse of mitral disease was to be explained by the observation that in these cases of mitral disease there was a ventricular inception of the heart beat. To illustrate these and other points Dr. Mackenzie showed a series of tracings. He also showed a heart dissected to display with great clearness the auriculo-ventricular bundle.—In the discussion which followed Professor A. R. CUSHNY spoke of the immense value of the accurate scientific observations made at the bedside by Dr. Mackenzie. The difficulty of the subject was very great. Even in experimental work with the same dose of digitalis, given in the same way to the same animal, the results varied widely from time to time.—Dr. H. C. CAMERON asked whether Dr. Mackenzie's work had led him to form any opinion as to the rapidity with which digitalis acted.—Dr. MACKENZIE, in reply, stated that as a rule the characteristic changes in tracings due to digitalis were not apparent for about 10 days.

Dr. W. SOPER then read an interesting paper on Reminiscences of an Apprentice 60 Years Ago. He described the forms of treatment which prevailed 60 years ago and compared them with more modern methods. The system of apprenticeship, he maintained, had many advantages.

UNITED SERVICES MEDICAL SOCIETY.

Recent Work on the Cause, Prevention, and Treatment of Mediterranean, or Undulant, Fever.

A MEETING of this society was held on Dec. 12th, 1907, Sir HERBERT M. ELLIS, the President, being in the chair.

Fleet-Surgeon P. W. BASSETT-SMITH, R.N., in a paper on the above subject gave an interesting historical *résumé* of the work that had been done in late years, more especially under the auspices of the tropical diseases committee of the Royal Society. This work was divided into experimental, epidemiological, and prophylactic. Under the first head he instanced the work of Horrocks, Shaw, himself, and others on the life-history and identification of the micrococcus Melitensis and its recovery from the blood and other secretions, and also experiments directed towards discovering the channels by which infection was conveyed in this disease. Under the heading of epidemiology were mentioned the reports of Davies and Johnstone, and under prophylaxis the work of Eyre and Shaw on sera, antisera, and toxins. The most important points brought out step by step were: (1) the great vitality of the organism outside the body when not exposed to direct sunlight; (2) the constant presence of the organism in the peripheral blood of cases suffering from the disease; (3) the escape of the organism from the body chiefly through the urine; (4) the presence of the infective organism in the urine of apparently healthy men; (5) frequent infection of domestic animals, chiefly goats; (6) infectivity of the urine and milk of these animals; (7) the high incidence of cases in patients and staff of hospitals; (8) the high incidence in officers, women, and children; (9) occurrence of localised epidemics; (10) rare recovery of the organism from local mosquitoes and very doubtful possibility of their being distributors of the disease; and (11) complete cessation of cases where infected milk was removed from the dietary or when it was properly sterilised. The prevention of the disease by "protective inoculations" still remained *sub judice.* As regards treatment he had little to say in favour of antisera or vaccines, though in chronic cases the latter seemed to have some slight beneficial effect. No specific drug had yet been discovered, quinine in large doses was harmful, cyllin was disappointing, fresh yeast was inoperative, and quinine combined with chlorine water was very uncertain in its results. Symptomatic treatment might, however, do much to relieve the insomnia and the persistent neuritis of the later stages. For this Fleet-Surgeon Bassett Smith recommended salicylate of quinine, while arsenic and iron were of use in the later cachexia and strychnine for irritable heart should this be a sequela. Touching briefly on pathology he pointed out that the evidence in favour of a general septicæmic infection was very strong, the organism being recoverable not only from the peripheral blood but also from the internal organs. In one case he had known an infective endocarditis to develop. Local lesions also occasionally occurred, sometimes in the form of soft fluctuating swellings, not containing pus but a turbid fluid from which the characteristic organism could be isolated. Ulceration of the small intestine and enlargement of the liver and spleen in chronic cases were also found.

Lieutenant-Colonel W. B. LEISHMAN, R.A.M.C., considered that it was very desirable that investigation should be directed towards ascertaining the line of communication from diseased to healthy goats. He suggested that the disease might be attacked by immunising these animals by means of injection of attenuated cultures of the micrococcus, pointing out that good results had been achieved by this method in other diseases—e.g., in cholera by Haffkine and more lately by Strong of Manila in the case of plague.

Lieutenant-Colonel A. M. DAVIES, R.A.M.C., quoted instances which inclined him to doubt whether milk was the only source of infection in this disease, and thought that the mosquito might still be found to play a part in its dissemination.

Lieutenant-Colonel D. V. O'CONNELL, R.A.M.C., was inclined to agree with the former speaker. He considered opium and morphine as being of great value in treatment but condemned the bromides as useless.

Fleet-Surgeon BASSETT-SMITH, in replying, said he thought that the Maltese would raise no objection to immunisation experiments amongst goats if threatened with destruction of infected animals. He thought that the remarkable success of the Malta Fever Commission was a strong argument in favour of experiments on animals, since without these the work of the Commission could never have been carried out.

The PRESIDENT then proposed a vote of thanks to Fleet-Surgeon Bassett-Smith for his interesting paper, which was carried by acclamation. The proceedings terminated with an exhibition of objects of interest in the Pathological Laboratory of the Royal Army Medical College.

LIVERPOOL MEDICAL INSTITUTION.

Exhibition of Cases and Specimens.—Plastic Roentgenography.—Method of Inflation of the Bladder with Oxygen.—Life History of Leucocytes.

A MEETING of this society was held on Dec. 12th, 1907, Mr. FRANK T. PAUL, the President, being in the chair.

Dr. G. G. STOPFORD TAYLOR and Dr. F. P. WILSON showed a specimen from a case of Enchondroma Cutis.—Dr. WILSON stated that the specimen had been taken from a female child. The mother had had a hæmorrhage during pregnancy and had been delivered a month before full time. When the child was about five months old the mother noticed a bluish stain on the inner side of the left leg just above the knee. This gradually developed into a hard plate. Similar plates subsequently appeared in the skin of other parts of the body. The specimen shown was taken from a plate over the right costal arch. It was so calcified in parts that a considerable effort was required to cut through it with a scalpel. A microscopical examination showed that the epidermis was normal. The corium was somewhat thickened and contained sweat glands with rudimentary hair follicles. In the deepest part of the corium were large irregular blocks of cartilage containing small cartilage cells and fenestrated here and there by spaces filled with a vascular connective tissue. In parts the cartilage seemed to merge indefinitely with the fibrous tissue of the corium. Dr. Wilson then commented on the extreme rarity of enchondromata of the skin and the fact that none of the cases hitherto recorded resembled the present one which was remarkable for the number of the new growths.—Dr. STOPFORD TAYLOR said that clinically the disease was one of cartilaginous plates imbedded in the corium at various depths, and that in one plaque on the outside of the left thigh distinct ossific spicules could be seen and felt, stretching the epidermis.—Dr. R. W. MACKENNA said that the plaques were distinctly cartilaginous but were undergoing ossification. The condition was an extremely rare one and he had only been able to find one similar case in literature which was associated with fragilitas ossium and which ultimately degenerated into sarcoma.—Dr. F. H. BARENDT believed the tumour to have originated in the subcutaneous tissue and to have grown into the cutis vera. The fact that the corium was implicated in the growing ends supported this view, as well as the islets of sweat glands and adipose tissue embraced by the tumour. He regarded the tumour as bony in nature and thought that there were distinct appearances of attempts at a Haversian system. Other portions of the section no doubt favoured the cartilaginous view which Dr. Wilson and others held. Possible dislocation of temporary cartilage during the development of the bones was the primary source of this rare condition and subsequent ossification.

Dr. NATHAN RAW showed a specimen of Carcinoma of Both Suprarenal Glands and Root of the Left Lung.—Dr. A. G. GULLAN said that he considered Dr. Raw's specimen of bilateral carcinoma of the suprarenal organs of special interest and importance because, although the suprarenals had been almost completely replaced by new growth, the patient had not shown symptoms or manifestations of Addison's disease. This case thus supported the view which he felt inclined to believe—i.e., that Addison's disease was the result of tuberculous lesions of the suprarenal and their sequelæ and was not due to other pathological affections of the organ.—Dr. BRADSHAW said that in the case of a patient with malignant disease it was not an easy matter to determine whether the symptoms of Addison's disease were present or not. Pigmentation was not a constant symptom in Addison's disease and the other symptoms of that condition, asthenia and gastric irritability, if they were met with in a patient known to be suffering from malignant disease in any part of the body would probably be looked on as symptomatic of the cancer and not as due to the special involvement of the suprarenal bodies.

Dr. DAVID MORGAN read a note on Plastic Roentgenography and showed several photographs and lantern slides of this new method. He described fully the methods of producing the plastic effect, for the discovery of which they were indebted to Dr. Béla Alexander of Késmárk, Hungary.

Dr. MORGAN also demonstrated the Method of Inflation of the Bladder with Oxygen for the purpose of diagnosis in vesical trouble and showed a photograph of stone in the bladder obtained by this method. The radiograph displayed the structure of the stone and the outlines of the bladder with remarkable distinctness. The oxygen inflation Dr. Morgan considered to be of great value in elucidating obscure affections of the bladder. Owing to the transparency of the medium (oxygen) any irregularity of the vesical mucosa would be readily discernible.

Dr. RAW showed a specimen of Tuberculosis of Fish.—Dr. R. E. HARCOURT considered that the proof was not sufficient to say that it was the tubercle bacillus, since the Ziehl-Neelsen acid fast staining acted in leprosy as well, and under the microscope it was scarcely possible to distinguish between the two bacilli. Again, Jonathan Hutchinson's theory that leprosy was caused by eating uncooked putrid fish might point to this being the bacillus lepræ and not tuberculosis.

The PRESIDENT showed specimens of Myeloid Tumours.—Dr. HARCOURT stated that in the early part of the year he was shown a section from a tumour of the lung which was said to be secondary to a myeloid tumour of the lower jaw. As the section was certainly a myeloid growth these tumours must be considered to be more malignant than was generally taught, as some authors (e.g., Mr. J. Bland-Sutton) taught that they were so benign that they placed them in a separate class, the myelomata.

Mr. C. E. WALKER read a paper on the Life History of Leucocytes. He described how some of the leucocytes in the bone marrow of mammals passed through the meiotic phase—that is, the number of chromosomes they exhibited when dividing was reduced to one-half of the normal somatic number. He drew a comparison between this phenomenon and what happened in the case of certain cells in plants. He then went on to describe how in some leucocytes which had not passed through this phase granules were developed in the cytoplasm. His observations upon the derivation of the granules in leucocytes were communicated in a paper sent to the Royal Society in July, 1906. He described a small coiled-up thread as arising in the archoplasm of these leucocytes. This thread grew until it occupied the whole of the cytoplasm and completely surrounded the nucleus. It then broke up into a number of short segments which subsequently assumed an oval or a round shape. The bulk of the cells which had passed through the meiotic phase he described as being converted into red corpuscles in the bone marrow. He showed that the series of changes which he described as occurring in these reduced leucocytes were completely checked by what could be observed actually happening under the microscope in the case of the red corpuscle of amphibia, reptiles, and birds. He pointed out that the condition of the leucocytes which were reduced was exactly similar to that of the sexual elements, in that these cells had gone through the necessary preparatory changes for fertilisation. In plants only a few of the cells which reduced ever conjugated with other reduced cells; the bulk of them merely served a nutritive purpose. Thus the fact that the bulk of the cells was converted into red corpuscles was just what happened in the case of many plants. He then described what he claimed to be a process of fertilisation occurring among a few of the reduced leucocytes. Two adjacent leucocytes sent out processes from their nuclei which join, forming a tube. The contents of one nucleus then passed over through this tube into the other nucleus, leaving one cell with a nuclear membrane devoid of linin and chromatin and the other with a double complement. He showed that this process was very different from the destruction of one cell by another. The latter phenomenon was very common but seemed always to take the form of engulfment of the whole or part of the cell destined to destruction into the cytoplasm of another cell. The usual sequence was that one leucocyte or other kind of cell engulfed another bodily into its cytoplasm; the engulfed cell was then gradually disintegrated, but was never taken into the nucleus but remained in the cytoplasm of the engulfing cell. Here the absorption of the contents of one leucocyte nucleus by that of another seemed to involve the development of a special and complicated apparatus, formed in such a manner that the chromatin and linin of the one nucleus might be transferred directly to the other without any process of digestion by the cytoplasm being possible. Mr. Walker therefore concluded that the phenomenon which he described was a process of fertilisation. From this he further concluded that the leucocytes passing out of coördination with the soma lived as parasites upon the parent organism, and in themselves possessed a complete life cycle.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

Hæmatoma of both Broad Ligaments.—Gonorrhœa and Uterine Sepsis.—Cæsarean Section for Pelvic Deformity.—Diffuse Adenoma.—Primary Unilateral Superficial Papilloma of the Ovary.—Supports of the Pelvic Viscera.

A MEETING of this society was held at Manchester on Dec. 20th, 1907, Dr. E. O. CROFT (Leeds), the President, being in the chair.

Dr. W. WALTER (Manchester) related a case of Hæmatoma of both Broad Ligaments occurring a few hours after a supravaginal hysterectomy on a patient, aged 37 years, who was exhausted by prolonged metrorrhagia. The tumour grew from the posterior wall of the uterus and extended laterally to the sides of the pelvis. Incising the uterus deeply the myoma was enucleated from its attachments but general oozing from the broad ligaments gave trouble. The pulse was 84 at the completion of the operation, four hours later it was 96, and at 6 P.M. it was 116 and a small amount of blood was coming through the vagina. At 8 P.M. the patient became collapsed and complained of abdominal pain. Saline injections were given, ether was administered, and the abdomen was opened. Not more than eight ounces of free blood were found in the abdomen, but both broad ligaments were distended with blood and clots. There was no bleeding apparent from the main vessels nor had their ligatures slipped. The collapse, simulating extensive hæmorrhage, was the chief interest in this case and may have been due to intense pain from over-distension of the ligaments in a patient already debilitated by previous hæmorrhage. Particulars were also given of a case of Abdominal Distension arising the day after supravaginal hysterectomy had been performed on a single woman, aged 40 years, who sought relief on account of excessive menorrhagia and retention of urine, produced by a myoma. The operation took place on Oct. 29th in the Trendelenburg position. Three hours afterwards the pulse was 68 and the patient was fairly comfortable. On the day following the abdomen was slightly distended and flatus could not be passed voluntarily. The pulse gradually rose and in the evening it was 130; vomiting and pain were troublesome and nutritive enemata were no longer retained. On the third day symptoms were more pronounced and the pulse was 152. It was decided to open the abdomen unless some improvement took place. At 8 P.M. one of the enemas took slight effect and the pulse fell to 140 and on the next day it was 128. Hot fomentations and gentle massage aided the ordinary treatment by enemata and calomel. The obstruction was possibly due to a kinking of the intestine when being replaced after Trendelenburg's position. Both cases made good recoveries.

Sir WILLIAM J. SINCLAIR (Manchester) mentioned a case of Gonorrhœa and Uterine Sepsis occurring in a patient aged 28 years, who had been married for seven years and had had one abortion. Curettage and removal of the uterine appendages had been previously carried out. The patient sought his advice for constant abdominal pain and on Nov. 15th he extirpated the uterus per vaginam. Steady and continued improvement followed. He advocated conservative measures from the outset in these cases.

Dr. J. LLOYD ROBERTS (Manchester) related two cases in which he had performed Cæsarean Section for Pelvic Deformity. In one the patient had had eight pregnancies. Craniotomy had been necessary five times and premature labour was induced twice, the child being stillborn on both occasions. Four years ago Cæsarean section was successfully performed and now for the second time. It was interesting to note that there was no union between the uterus and the parietes following the first operation. In the second case craniotomy had been performed once. Both patients made uneventful recoveries.

Dr. ARNOLD W. W. LEA (Manchester) narrated two cases of Diffuse Adenoma occurring in Fibroid Uteri and drew attention to the features of pathological interest in this condition. Multiple polypoid projections of the endometrium, microscopically of a benign character, were present. The uterine wall was uniformly thickened to the extent of two inches in some situations. The specimens and microscopical sections were also shown.

Dr. E. EMRYS ROBERTS (Liverpool) gave a pathological report, illustrated by lantern slides, on a case of Primary Unilateral Superficial Papilloma of the Ovary and expressed the view that the ascites present in such cases was the result of secretion by the epithelium covering the papillæ. The tumour was removed by Professor H. Briggs in the Hospital for Women at Liverpool.

Dr. JOHN CAMERON (Manchester) exhibited a number of dissections demonstrating the Supports of the Pelvic Viscera. After pointing out that the muscles forming the pelvic floor in man were now recognised as vestigial structures he directed attention to the fact that they must regard the fascia surrounding the visceral branches of the internal iliac vessels (the perivascular fascia) as forming the most important support of the pelvic viscera both in the male and in the female. He then went on to suggest that operative treatment for prolapsus uteri must be directed not to the pelvic outlet alone but also to this perivascular fascia.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

Diphtheritic Fever.—Eye Strain.

A MEETING of this section was held on Dec. 6th, 1907, Dr. A. R. PARSONS being in the chair.

Sir JOHN W. MOORE gave details respecting a remarkable outbreak of sore-throat which had come under his observation in a large girls' school in Dublin during the autumn of 1906. Bacteriological examination proved the outbreak to be due to an infection with a form of the Klebs-Löffler bacillus diphtheriæ. The resulting illness failed to present the typical features of classical diphtheria—it might be described as "diphtheroid," and he had ventured to call it "diphtheritic fever." From Oct. 2nd to Nov. 11th, 1906, out of a total of 43 girls in the school 18 were attacked—that is, 41·9 per cent. There were five distinct outbreaks. In the first, one girl sickened on Oct. 2nd; in the second, one girl sickened on Oct. 10th; in the third, two girls sickened on Oct. 19th, two on the 21st, two on the 22nd, two on the 23rd, and one on the 24th; in the fourth, one girl was attacked on Oct. 28th, two on the 29th, one on Nov. 1st, and one on the 2nd; and in the fifth, one girl was attacked on Nov. 7th (for the second time), one on the 8th, and one on the 11th. After this last date no further cases occurred for a long time. Diphtheria was carried home to the country in two instances by the girls when, nearly two months after their illness, the school broke up for the Christmas holidays. Nearly 12 months afterwards a little epidemic of a precisely similar nature occurred in the school. On Sept. 30th, 1907, three cases of sore-throat occurred in the school; the patients were moderately feverish, with swollen tonsils and enlarged cervical glands but little or no exudation. A bacteriological examination, made by Dr. W. Boxwell on Oct. 1st, showed that the milder form of the diphtheria bacillus was present in considerable quantities in two of the three cases. In the third case—clinically the most severe—Dr. Boxwell failed to find it, probably because streptococci and staphylococci were so numerous that they crowded out, as it were, the Klebs-Löffler bacilli—a fact well known in true diphtheria. Lastly, the symptoms which by their more or less constant presence made up the clinical syndrome of diphtheritic fever were: (1) a more or less severe coryza; (2) a moderate tonsillitis, usually one-sided, and unattended by high fever or by much exudation; (3) thickly coated tongue and foul breath, the tongue desquamating as in scarlet fever; (4) a patchy or punctate rash on the roof of the mouth and buccal mucous membrane; (5) swelling of the cervical lymphatic glands; (6) a roseolar rash on the skin; and (7) distinct desquamation (in three cases), the peeling being particularly marked on the hands.—Dr. T. P. C. KIRKPATRICK said that sometimes 10 or 11 recruits came into Steevens' Hospital, Dublin, in one day from the Constabulary Depôt, complaining of symptoms resembling those described by Sir John Moore. They usually recovered in a short time. In no case had there been any suspicion of membrane, and bacteriological examination showed no trace of the diphtheria bacillus in many cases. The organism in the majority of cases was some form of coccus. The condition was looked upon as an epidemic of catarrh and in no case had the roseolar rash or enlargement of the cervical glands been observed.—Mr. JOHN BURGESS said that the recruits mentioned by Dr. Kirkpatrick were brought up from the country and were not used to the ordinary hygiene. They were given swimming lessons and kept in the water for half an hour or more. This chilled them and they complained of sore-throats.—Dr. J. M. DAY said that it was not necessary to find a membrane to diagnose diphtheria. He had pointed out in a paper some years ago that cases having soft tonsils, coated tongue, and enlarged glands had given the diphtheria bacillus on a swab. Diphtheria was much commoner in the city than people supposed and there were two main predisposing causes—namely, bad teeth and constipation.

Dr. KIRKPATRICK read a paper on Eye Strain as a Factor in the Production of Functional Neuroses. One patient to whom he referred had complained for years of recurrent attacks of migraine and though he made no complaint of his vision his condition was completely relieved by the correction of some faulty muscle balance of his eyes. Cases were also quoted to show the advantage of the correction of errors of refraction in the relief of persistent headache. A patient who had complained of severe and more or less persistent headache for nearly 15 years was completely relieved by the use of proper correcting glasses.

Dr. HERBERT C. MOONEY read a paper on Eye Strain, in which he expressed the opinion that the relation between headaches and errors of refraction was not as fully realised by physicians as it might be. He pointed out the part played by errors of refraction, accommodation, and the balance of the extrinsic muscles of the eye in the causation of headache, migraine, giddiness, and nausea, and said that of enchondromata of the skin and the fact that none of the cases hitherto recorded resembled the present one which was remarkable for the number of the new growths.—Dr. STOPFORD TAYLOR said that clinically the disease was one of cartilaginous plates imbedded in the corium at various depths, and that in one plaque on the outside of the left thigh distinct ossific spicules could be seen and felt, stretching the epidermis.—Dr. R. W. MACKENNA said that the plaques were distinctly cartilaginous but were undergoing ossification. The condition was an extremely rare one and he had only been able to find one similar case in literature which was associated with *fragilitas ossium* and which ultimately degenerated into sarcoma.—Dr. F. H. BARENDT believed the tumour to have originated in the subcutaneous tissue and to have grown into the cutis vera. The fact that the corium was implicated in the growing ends supported this view, as well as the islets of sweat glands and adipose tissue embraced by the tumour. He regarded the tumour as bony in nature and thought that there were distinct appearances of attempts at a Haversian system. Other portions of the section no doubt favoured the cartilaginous view which Dr. Wilson and others held. Possible dislocation of temporary cartilage during the development of the bones was the primary source of this rare condition and subsequent ossification.

Dr. NATHAN RAW showed a specimen of Carcinoma of Both Suprarenal Glands and Root of the Left Lung.—Dr. A. G. GULLAN said that he considered Dr. Raw's specimen of bilateral carcinoma of the suprarenal organs of special interest and importance because, although the suprarenals had been almost completely replaced by new growth, the patient had not shown symptoms or manifestations of Addison's disease. This case thus supported the view which he felt inclined to believe—i.e., that Addison's disease was the result of tuberculous lesions of the suprarenal and their sequelæ and was not due to other pathological affections of the organ.—Dr. BRADSHAW said that in the case of a patient with malignant disease it was not an easy matter to determine whether the symptoms of Addison's disease were present or not. Pigmentation was not a constant symptom in Addison's disease and the other symptoms of that condition, asthenic and gastric irritability, if they were met with in a patient known to be suffering from malignant disease in any part of the body would probably be looked on as symptomatic of the cancer and not as due to the special involvement of the suprarenal bodies.

Dr. DAVID MORGAN read a note on Plastic Roentgenography and showed several photographs and lantern slides of this new method. He described fully the methods of producing the plastic effect, for the discovery of which they were indebted to Dr. Béla Alexander of Késmárk, Hungary.

Dr. MORGAN also demonstrated the Method of Inflation of the Bladder with Oxygen for the purpose of diagnosis in vesical trouble and showed a photograph of stone in the bladder obtained by this method. The radiograph displayed the structure of the stone and the outlines of the bladder with remarkable distinctness. The oxygen inflation Dr. Morgan considered to be of great value in elucidating obscure affections of the bladder. Owing to the transparency of the medium (oxygen) any irregularity of the vesical mucosa would be readily discernible.

Dr. RAW showed a specimen of Tuberculosis of Fish.—Dr. R. E. HARCOURT considered that the proof was not sufficient to say that it was the tubercle bacillus, since the Ziehl-Neelsen acid fast staining acted in leprosy as well, and under the microscope it was scarcely possible to distinguish between the two bacilli. Again, Jonathan Hutchinson's theory that leprosy was caused by eating uncooked putrid fish might point to this being the bacillus lepræ and not tuberculosis.

The PRESIDENT showed specimens of Myeloid Tumours.—Dr. HARCOURT stated that in the early part of the year he was shown a section from a tumour of the lung which was said to be secondary to a myeloid tumour of the lower jaw. As the section was certainly a myeloid growth these tumours must be considered to be more malignant than was generally taught, as some authors (e.g., Mr. J. Bland-Sutton) taught that they were so benign that they placed them in a separate class, the myelomata.

Mr. C. E. WALKER read a paper on the Life History of Leucocytes. He described how some of the leucocytes in the bone marrow of mammals passed through the meiotic phase—that is, the number of chromosomes they exhibited when dividing was reduced to one-half of the normal somatic number. He drew a comparison between this phenomenon and what happened in the case of certain cells in plants. He then went on to describe how in some leucocytes which had not passed through this phase granules were developed in the cytoplasm. His observations upon the derivation of the granules in leucocytes were communicated in a paper sent to the Royal Society in July, 1906. He described a small coiled-up thread as arising in the archoplasm of these leucocytes. This thread grew until it occupied the whole of the cytoplasm and completely surrounded the nucleus. It then broke up into a number of short segments which subsequently assumed an oval or a round shape. The bulk of the cells which had passed through the meiotic phase he described as being converted into red corpuscles in the bone marrow. He showed that the series of changes which he described as occurring in these reduced leucocytes were completely checked by what could be observed actually happening under the microscope in the case of the red corpuscle of amphibia, reptiles, and birds. He pointed out that the condition of the leucocytes which were reduced was exactly similar to that of the sexual elements, in that these cells had gone through the necessary preparatory changes for fertilisation. In plants only a few of the cells which reduced ever conjugated with other reduced cells; the bulk of them merely served a nutritive purpose. Thus the fact that the bulk of the cells was converted into red corpuscles was just what happened in the case of many plants. He then described what he claimed to be a process of fertilisation occurring among a few of the reduced leucocytes. Two adjacent leucocytes sent out processes from their nuclei which join, forming a tube. The contents of one nucleus then passed over through this tube into the other nucleus, leaving one cell with a nuclear membrane devoid of linin and chromatin and the other with a double complement. He showed that this process was very different from the destruction of one cell by another. The latter phenomenon was very common but seemed always to take the form of engulfment of the whole or part of the cell destined to destruction into the cytoplasm of another cell. The usual sequence was that one leucocyte or other kind of cell engulfed another bodily into its cytoplasm; the engulfed cell was then gradually disintegrated, but was never taken into the nucleus but remained in the cytoplasm of the engulfing cell. Here the absorption of the contents of one leucocyte nucleus by that of another seemed to involve the development of a special and complicated apparatus, formed in such a manner that the chromatin and linin of the one nucleus might be transferred directly to the other without any process of digestion by the cytoplasm being possible. Mr. Walker therefore concluded that the phenomenon which he described was a process of fertilisation. From this he further concluded that the leucocytes passing out of coördination with the soma lived as parasites upon the parent organism, and in themselves possessed a complete life cycle.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

Hæmatoma of both Broad Ligaments.—Gonorrhœa and Uterine Sepsis.—Cæsarean Section for Pelvic Deformity.—Diffuse Adenoma.—Primary Unilateral Superficial Papilloma of the Ovary.—Supports of the Pelvic Viscera.

A MEETING of this society was held at Manchester on Dec. 20th, 1907, Dr. E. O. CROFT (Leeds), the President, being in the chair.

Dr. W. WALTER (Manchester) related a case of Hæmatoma of both Broad Ligaments occurring a few hours after a supravaginal hysterectomy on a patient, aged 37 years, who was exhausted by prolonged metrorrhagia. The tumour grew from the posterior wall of the uterus and extended laterally to the sides of the pelvis. Incising the uterus deeply the myoma was enucleated from its attachments but general oozing from the broad ligaments gave trouble. The pulse was 84 at the completion of the operation, four hours later it was 96, and at 6 P.M. it was 116 and a small amount of blood was coming through the vagina. At 8 P.M. the patient became collapsed and complained of abdominal pain. Saline injections were given, ether was administered, and the abdomen was opened. Not more than eight ounces of free blood were found in the abdomen, but both broad ligaments were distended with blood and clots. There was no bleeding apparent from the main vessels nor had their ligatures slipped. The collapse, simulating extensive hæmorrhage, was the chief interest in this case and may have been due to intense pain from over-distension of the ligaments in a patient already debilitated by previous hæmorrhage. Particulars were also given of a case of Abdominal Distension arising the day after supravaginal hysterectomy had been performed on a single woman, aged 40 years, who sought relief on account of excessive menorrhagia and retention of urine, produced by a myoma. The operation took place on Oct. 29th in the Trendelenburg position. Three hours afterwards the pulse was 88 and the patient was fairly comfortable. On the day following the abdomen was slightly distended and flatus could not be passed voluntarily. The pulse gradually rose and in the evening it was 130; vomiting and pain were troublesome and nutritive enemata were no longer retained. On the third day symptoms were more pronounced and the pulse was 152. It was decided to open the abdomen unless some improvement took place. At 8 P.M. one of the enemas took slight effect and the pulse fell to 140 and on the next day it was 128. Hot fomentations and gentle massage aided the ordinary treatment by enemata and calomel. The obstruction was possibly due to a kinking of the intestine when being replaced after Trendelenburg's position. Both cases made good recoveries.

Sir WILLIAM J. SINCLAIR (Manchester) mentioned a case of Gonorrhœa and Uterine Sepsis occurring in a patient aged 28 years, who had been married for seven years and had had one abortion. Curettage and removal of the uterine appendages had been previously carried out. The patient sought his advice for constant abdominal pain and on Nov. 15th he extirpated the uterus per vaginam. Steady and continued improvement followed. He advocated conservative measures from the outset in these cases.

Dr. J. LLOYD ROBERTS (Manchester) related two cases in which he had performed Cæsarean Section for Pelvic Deformity. In one the patient had had eight pregnancies. Craniotomy had been necessary five times and premature labour was induced twice, the child being stillborn on both occasions. Four years ago Cæsarean section was successfully performed and now for the second time. It was interesting to note that there was no union between the uterus and the parietes following the first operation. In the second case craniotomy had been performed once. Both patients made uneventful recoveries.

Dr. ARNOLD W. W. LEA (Manchester) narrated two cases of Diffuse Adenoma occurring in *Fibroid Uteri* and drew attention to the features of pathological interest in this condition. Multiple polypoid projections of the endometrium, microscopically of a benign character, were present. The uterine wall was uniformly thickened to the extent of two inches in some situations. The specimens and microscopical sections were also shown.

Dr. E. EMRYS ROBERTS (Liverpool) gave a pathological report, illustrated by lantern slides, on a case of Primary Unilateral Superficial Papilloma of the Ovary and expressed the view that the ascites present in such cases was the result of secretion by the epithelium covering the papillæ. The tumour was removed by Professor H. Briggs in the Hospital for Women at Liverpool.

Dr. JOHN CAMERON (Manchester) exhibited a number of dissections demonstrating the Supports of the Pelvic Viscera. After pointing out that the muscles forming the pelvic floor in man were now recognised as vestigial structures he directed attention to the fact that they must regard the fascia surrounding the visceral branches of the internal iliac vessels (the perivascular fascia) as forming the most important support of the pelvic viscera both in the male and in the female. He then went on to suggest that operative treatment for prolapsus uteri must be directed not to the pelvic outlet alone but also to this perivascular fascia.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

Diphtheritic Fever.—Eye Strain.

A MEETING of this section was held on Dec. 6th, 1907, Dr. A. R. PARSONS being in the chair.

Sir JOHN W. MOORE gave details respecting a remarkable outbreak of sore-throat which had come under his observation in a large girls' school in Dublin during the autumn of 1906. Bacteriological examination proved the outbreak to be due to an infection with a form of the Klebs-Löffler bacillus diphtheriæ. The resulting illness failed to present the typical features of classical diphtheria—it might be described as "diphtheroid," and he had ventured to call it "diphtheritic fever." From Oct. 2nd to Nov. 11th, 1906, out of a total of 43 girls in the school 18 were attacked—that is, 41·9 per cent. There were five distinct outbreaks. In the first, one girl sickened on Oct. 2nd; in the second, one girl sickened on Oct. 10th; in the third, two girls sickened on Oct. 19th, two on the 21st, two on the 22nd, two on the 23rd, and one on the 24th; in the fourth, one girl was attacked on Oct. 28th, two on the 29th, one on Nov. 1st, and one on the 2nd; and in the fifth, one girl was attacked on Nov. 7th (for the second time), one on the 8th, and one on the 11th. After this last date no further cases occurred for a long time. Diphtheria was carried home to the country in two instances by the girls when, nearly two months after their illness, the school broke up for the Christmas holidays. Nearly 12 months afterwards a little epidemic of a precisely similar nature occurred in the school. On Sept. 30th, 1907, three cases of sore-throat occurred in the school; the patients were moderately feverish, with swollen tonsils and enlarged cervical glands but little or no exudation. A bacteriological examination, made by Dr. W. Boxwell on Oct. 1st, showed that the milder form of the diphtheria bacillus was present in considerable quantities in two of the three cases. In the third case—clinically the most severe—Dr. Boxwell failed to find it, probably because streptococci and staphylococci were so numerous that they crowded out, as it were, the Klebs-Löffler bacilli—a fact well known in true diphtheria. Lastly, the symptoms which by their more or less constant presence made up the clinical syndrome of diphtheritic fever were: (1) a more or less severe coryza; (2) a moderate tonsillitis, usually one-sided, and unattended by high fever or by much exudation; (3) thickly coated tongue and foul breath, the tongue desquamating as in scarlet fever; (4) a patchy or punctate rash on the roof of the mouth and buccal mucous membrane; (5) swelling of the cervical lymphatic glands; (6) a roseolar rash on the skin; and (7) distinct desquamation (in three cases), the peeling being particularly marked on the hands.—Dr. T. P. C. KIRKPATRICK said that sometimes 10 or 11 recruits came into Steevens' Hospital, Dublin, in one day from the Constabulary Depôt, complaining of symptoms resembling those described by Sir John Moore. They usually recovered in a short time. In no case had there been any suspicion of membrane, and bacteriological examination showed no trace of the diphtheria bacillus in many cases. The organism in the majority of cases was some form of coccus. The condition was looked upon as an epidemic of catarrh and in no case had the roseolar rash or enlargement of the cervical glands been observed.—Mr. JOHN BURGESS said that the recruits mentioned by Dr. Kirkpatrick were brought up from the country and were not used to the ordinary hygiene. They were given swimming lessons and kept in the water for half an hour or more. This chilled them and they complained of sore-throats.—Dr. J. M. DAY said that it was not necessary to find a membrane to diagnose diphtheria. He had pointed out in a paper some years ago that cases having soft tonsils, coated tongue, and enlarged glands had given the diphtheria bacillus on a swab. Diphtheria was much commoner in the city than people supposed and there were two main predisposing causes—namely, bad teeth and constipation.

Dr. KIRKPATRICK read a paper on Eye Strain as a Factor in the Production of Functional Neuroses. One patient to whom he referred had complained for years of recurrent attacks of migraine and though he made no complaint of his vision his condition was completely relieved by the correction of some faulty muscle balance of his eyes. Cases were also quoted to show the advantage of the correction of errors of refraction in the relief of persistent headache. A patient who had complained of severe and more or less persistent headache for nearly 15 years was completely relieved by the use of proper correcting glasses.

Dr. HERBERT C. MOONEY read a paper on Eye Strain, in which he expressed the opinion that the relation between headaches and errors of refraction was not as fully realised by physicians as it might be. He pointed out the part played by errors of refraction, accommodation, and the balance of the extrinsic muscles of the eye in the causation of headache, migraine, giddiness, and nausea, and said that headaches met with in young students were often wrongly put down to the quality or quantity of the illuminant instead of to some degree, often quite small, of astigmatism.

Devon and Exeter Medico-Chirurgical Society.—A meeting of this society was held on Dec. 12th, 1907, Mr. R. Coombe, the President, being in the chair.—The President showed a boy, aged about 12 years, on whom he had successfully performed the operation of Submucous Resection of the Septum Nasi.—Dr. J. D. Harmer, house surgeon at the Royal Devon and Exeter Hospital, showed for Dr. J. Delpratt Harris a case of Actinomycosis of the Jaw. The patient, who was a girl aged 18 years, gave a history of three months' illness. The whole of the left side of the face was swollen and brawny and the eyelids were œdematous. There were several sinuses, from which exuded thick, yellow, offensive pus. She could only separate her teeth a short distance and was in a serious general condition, with quickened pulse and elevated temperature. She was by occupation a domestic servant in Exeter, but her father was a farm labourer and she was at home in the summer.—Dr. R. V. Solly showed a microscopic slide of the pus from the foregoing case, which exhibited branching mycelium but no clubs.—Dr. Solly read a paper on Leukæmia. He began by reporting the following cases which occurred in the Royal Devon and Exeter Hospital. The first patient was a man, aged 34 years, who had served in the Marines and had been to the tropics but had never been ill there. There was a history of syphilis four years ago. The present symptoms were anæmia, indigestion, and palpitation. The spleen reached nearly to Poupart's ligament. The patient's temperature was generally normal. The blood contained about 3,000,000 red cells and 340,000 white cells per cubic millimetre, with 40 per cent. polymorphs, 56 per cent. neutrophile, and 2·2 per cent. eosinophile myelocytes. The patient remained in the hospital for three months and was discharged unrelieved. The second and third patients were women, aged respectively 40 and 30 years; they both died within three months after coming under observation. The fourth case was one of acute lymphatic leukæmia, which was fully reported in The Lancet of June 23rd, 1906. The patient was a girl, aged 13 years, whose whole illness only lasted 14 days, and whose blood contained the enormous proportions of 796,000 white cells per cubic millimetre with only 1·6 per cent. polymorphs and 86 per cent. large and 11 per cent. small lymphocytes. Dr. Solly commenced his paper by stating that the diagnosis of leukæmia was almost entirely dependent on the blood examination. It was necessary, however, that a differential as well as a total leucocyte count should be made, as cases of leukæmia occurred in which the total count of the white cells was little raised above normal, but the differential character of the leucocytes was profoundly altered. Acute lymphatic leukæmia might give all the appearance of an acute infection and might have to be diagnosed by the blood examination from such diseases as typhoid fever or general septicæmia, and as it was almost invariably rapidly fatal it was well to make a diagnosis as soon as possible. Conditions such as splenic anæmia and lymphadenoma, where the leucocytes were little changed, were diagnosed immediately from leukæmia by a stained blood film, and the same could be said of enlargements of the liver and spleen due to syphilis or malaria. Spleno-medullary leukæmia, lymphatic leukæmia, and pernicious anæmia should be considered together as arising from some dyscrasia of the blood-forming organs, and particularly of the bone marrow. Dr. Solly then referred to cases described by Leube under the name of leukanæmia which exhibited the characters of leukæmia and pernicious anæmia combined. Dr. Solly gave it as his opinion that the most probable cause of pernicious anæmia and the leukæmias was some toxin acting in the bone marrow and possibly produced in the intestines, and causing in pernicious anæmia megaloblastic degeneration, destruction of red cells, and some myelocytosis, and in the leukæmias myelocytosis or lymphocytosis. The view that it was an intoxication was supported by the fact that both infection by the bothriocephalus latus and saponin poisoning produced megaloblastic degeneration as in pernicious anæmia. In these cases no improvement was produced by exposure to the x rays. In one case the spleen became smaller and the number of leucocytes diminished but the patient became more anæmic and shortly died. Dr. Solly suggested that the fresh bone marrow sandwich treatment as carried out by Dr. A. G. Gullan of Liverpool in pernicious anæmia might be tried in leukæmia.—Dr. W. Gordon in discussing the paper remarked that he felt certain that the large lymphocytes of acute lymphatic leukæmia were not the normal large lymphocytes of the blood, as these leukæmic lymphocytes frequently showed quite different staining characteristics, the normal lymphocytes having a dark nucleus and a lighter rim of protoplasm, while frequently in these abnormal lymphocytes of leukæmia the rim of protoplasm took the basic stain more deeply than the nucleus.

Sheffield Medico-Chirurgical Society.—A meeting was held in the society's room in the University on Dec. 19th, 1907, Dr. R Gordon being in the chair.—Professor J. M. Beattie showed the more interesting recent additions to the museum. These were accompanied by microscopic specimens and included specimens from cases of Delayed Chloroform Poisoning, Hæmochromatosis of the Liver in "Bronzed Diabetes," a Lung Full of "Sand" which the micro-section showed to be due to Calcified Corpora Amylacea, a section of the Liver from a case of Argyria showing Silver Deposit, Malaria Parasites, Lymphatic Leukæmia of the Kidney and Liver, a Kidney from a case of Hæmoglobinuria, Endothelioma of the Lung, and Fat Necrosis of the Omentum.—Dr. Arthur J. Hall showed specimens of Hæmorrhage into the Cerebellum and Cerebrum due to Purpura Hæmorrhagica, a Liver and Spleen Two Years after Epiplorrhaphy for Cirrhosis of the Liver, and other cases.—Dr. H. G. M. Henry showed a series of Cerebral Tumours and specimens from a case of Congenital Syphilis.—Dr. H. Leader showed Macro- and Micro-specimens from a case of Lympho-sarcoma.—Dr. W. H. Nutt showed a series of Skiagrams illustrating bronchiectasis, thickened pleuræ, pulmonary tuberculosis, renal calculi, intrathoracic growths, tumours, foreign bodies, fractures, and one of a child with absence of cervical vertebræ.—Dr. A. Rupert Hallam showed a series of Skiagrams illustrating fractures, foreign bodies, pulmonary tuberculosis, renal and ureteric calculi, and a stereoscopic view of a skiagram of the hand.—Mr. Arthur M Connell showed a series of Pathological Specimens and a number of enlargements of Micro-photographs which showed very clearly several varieties of carcinoma and perithelioma.—Mr. A. W. Cuff showed a Sarcoma of the Shoulder removed by Berger's Operation, a Renal Stone from Perforated Pyo-nephrosis, Anal Fistulæ which had been dissected out, and other specimens.—Mr. H. Lockwood showed specimens of Cystic Kidneys.—Mr. R. J. Pye-Smith showed a Glioma of the Brain with microscopic specimen.—Mr. A. Garrick Wilson showed a specimen of Calculous Nephritis in an Infant.—Dr. Percival J. Hay showed an Equatorial Staphyloma of the Sclera, Glioma of the Retina, a Rare Tumour of the Optic Nerve (Primary Glioma), Hydrophthalmos due to Ophthalmia Neonatorum, and a specimen showing Perforation of the Cornea and Mode of Infection of the Posterior Chamber.—Mr. Miles H. Phillips showed a collection of Gynæcological Specimens, consisting chiefly of those added to the museum during the year. There were six preparations of ectopic pregnancy, two of early rupture of the isthmial sacs, two tubal abortions, a five-weeks unruptured gestation in a rudimentary horn, and a full term unruptured sac, apparently tubal. Other important specimens illustrated "red degeneration" of a fibroid during pregnancy, abscess of the corpus luteum, cystic degeneration of fibroids, and a good example of a fibroid polypus of the vagina.—Dr. F. H. Waddy showed three interesting Uterine Moles from cases of Missed and Concealed Abortion and a Six-months Hydrocephalic Fœtus with Deficiency in the Fingers of One Hand, possibly due to intra-uterine amputation.

Clinical Society of Manchester.—A meeting of this society was held on Dec. 17th, 1907, Dr. H. R. Hutton, the President, being in the chair.—The meeting was devoted to the exhibition of cases.—Mr. E. Stanmore Bishop showed four cases of Gastro-enterostomy. Two of these had been done for ulceration of the stomach, one for ulceration of the duodenum, and one for hyperchlorhydria. One of these cases was that of a young woman who at the time of operation was much emaciated from constant vomiting and loss of blood. After operation she rapidly improved and gained three stones in weight in four months. In another symptoms of perforation had been noted a month previously. When the abdomen was opened the omentum was found adherent to a thickened ulcer in the anterior wall of the stomach. Posterior gastro-enterostomy was done and the patient lost all previous symptoms and rapidly increased in weight. Mr. Bishop described the evolution of the operation and pointed out the drawbacks of the earlier methods.—Dr. J. A. Knowles Renshaw showed: 1. A case of Papilloma of the Larynx. The patient, a female, aged 30 years, had suffered from hoarseness for three years. There had been no cough or discomfort; during the last year the hoarseness had not been so noticeable. On examination a small pedunculated growth was seen arising from the lower surface of the right cord at the junction of the anterior and middle third. On phonation the growth rose above the cords. The improvement in the voice which had latterly taken place was due, no doubt, to the increase in length of the pedicle which allowed this free movement of the growth. 2. A case of Ethmoiditis and Ulceration of the Septum Nasi. The patient, a woman, aged 32 years, complained of obstruction of the right nostril and swelling over the right nasal bone, which she attributed to a blow on the nose eight months since. There was a large amount of infiltration in the ethmoidal region, the middle turbinal being especially thickened. Over the septal cartilage was a shallow irregular ulcer, on the anterior edge of which were several small masses of granulation tissue. Although no definite history could be obtained the general appearance was strongly suggestive of specific disease. 3. A case of Chorditis Tuberosa. The patient, a woman, aged 25 years, had overstrained her voice by talking amid loud machinery. The node on the left cord was much larger than that on the right and was semi-translucent, having the appearance of a small myxoma.—Dr. G. H. Lancashire showed (1) three cases illustrating Different Phases of Lupus Erythematosus; (2) a case of Hereditary Syphilis in a girl, aged 14 years, rapidly responding to five-grain doses of iodide of potassium; and (3) a case of Molluscum Contagiosum. The back had been covered with an enormous number of lesions. Cure had been effected within a fortnight by expressing the contents of the tumour and rubbing in a 40 per cent. resorcin ointment.—Dr. R. W. Marsden, Dr. C. H. Melland, and Dr. C. C. Heywood also exhibited cases.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Dec. 18th, 1907, Dr. L. W. Marshall, the President, being in the chair.—Dr. Thomson Henderson gave a lantern demonstration illustrating some of his recent work on the Anatomy and Pathology of the Eye. He pointed out that the unity of pathological processes throughout the body was an important fact and pathological conditions in the eye obeyed the same laws that applied elsewhere. The only clinical or pathological differences observable resulted from the anatomical conditions peculiar to the eye as a special sense organ. After describing in detail the anatomy of the angle of the anterior chamber and the formation of the aqueous by the ciliary body it was demonstrated how the fluid drained away by Schlemm's canal assisted by the iris. By means of crypts on its surface the latter allowed the aqueous fluid to penetrate its stroma and so to come into direct contact with the veins of the iris. When the pupil contracted these crypts were widely open, but when it dilated these openings were closed and outflow by way of the iris was prevented. After demonstrating the venous connexions of Schlemm's canal Dr. Henderson discussed their bearing on glaucoma. He stated that the open network or cribriform ligament on the inner side of the venous sinus of Schlemm's canal became thickened in this disease so that the interspaces were reduced and free outflow of the aqueous was hindered and intraocular tension raised. This thickening was a physiological process going on throughout life and only in its results was the effect pathological. In virtue of its crypts the iris was an absorbing surface and the operation of iridectomy produced a large crypt—namely, three sides of a square, through which the aqueous readily escaped, as the cut surface of the normal iris never healed. The reason for this apparently startling fact was clear when they considered that cicatrisation was a protective process, resulting from the reaction of the cells of a tissue to irritation or to altered conditions of life. As a successful iridectomy did not alter the relation of the severed tissue cells to their immediate surroundings but left them still bathed by the aqueous, no stimulus was imparted to them to cause them to lay down a dense and protective layer. The iris tissue thus remained unaltered and presented a large raw surface, by means of which the aqueous could readily drain away provided the operation was done before atrophy and damage to its structure had proceeded too far.—The subject was discussed by Dr. F. H. Jacob, Dr. E. C. Kingdon, Dr. J. Watson, Dr. T. D. Pryce, and the President, and Dr. Henderson replied.

ÆSCULAPIAN SOCIETY.—A meeting of this society was held on Dec. 20th, 1907, Dr. W. Langdon Brown, the President, being in the chair.—Mr. Peter L. Daniel read a paper on Common Urinary Diseases and Some Points in their Etiology and Treatment. In the early stage of acute infection of a first attack of gonorrhœa the only germ present was the gonococcus. At the end of four or five weeks the infection of the gonococcus subsided and the urethra became aseptic and continued so for eight or ten days, but if not treated properly it got infected by streptococci and staphylococci which caused gleet. In the early stage of gonorrhœa the urine should be kept acid so as to inhibit the growth of the gonococci and prevent their spread from the anterior to the posterior urethra. For this the best drugs were urotropine or helmitol, and acid sodium phosphate, together with some preparation of sandal wood oil. The amount of liquids should be restricted so that drugs were given in a concentrated form. Local treatment should be started at once by injecting the anterior urethra alone, using a two-drachm Herring's syringe with solution of silver nitrate, 1 to 12 000, or potassium permanganate, 1 to 8000. Stricture was not produced by gonorrhœa itself but by added sepsis, so the secret of treatment was cleanliness. Enlarged prostate in most cases was the result of sepsis in the urethra. All other symptoms except difficulty in micturition and nocturnal frequency were due to sepsis setting up cystitis. Hence in enlarged prostate the cystitis should be treated. In kidney troubles, in order to get specimens of urine from different kidneys it was not necessary to catheterise the ureters, for a segregation answered perfectly well. Most kidney troubles were due to infection passing up along the "open door," so if the lower genito-urinary tract was kept clean there would be less kidney mischief.—Dr Herbert T. Herring said that nearly all urinary surgery was due to sepsis introduced by examination with dirty instruments. In treating a septic disease like gonorrhœa it was essential that instruments, hands, and penis were aseptic so as to prevent any fresh infection. It was almost impossible to get formation of phosphatic stones without sepsis.

SOUTH-WEST LONDON MEDICAL SOCIETY.—A meeting of this society was held on Dec. 11th, 1907, Dr. A. D Roe, the President, being in the chair.—Dr. Hector Mackenzie read a paper on the Treatment of Pneumonia and its Complications. After defining pneumonia as a local infection of the lung by the pneumococcus, accompanied or followed by the entrance of the micro-organism into the blood-stream, Dr. Mackenzie emphasised the importance of an abundant supply of fresh air in the treatment of all cases. In the past there had been three main forms of treatment, each of which had been successful in a measure: by bleeding, by brandy, and by the expectant treatment. The use of alcohol as a routine treatment was diminishing, but there were cases, especially among the old, where alcohol was of great benefit. Though bleeding was now out of fashion it was indicated in cases of marked cyanosis with cardiac dilatation; leeches, a dozen or more, might be employed in its place. Where there was prune-juice expectoration indicating œdema of the lungs and a watery condition of the blood calcium chloride should be given; in other conditions citrates were more useful. Oxygen had been much administered and greatly overrated, but it did no harm if no good. As to local applications, Dr. Mackenzie preferred hot to cold for the relief of pain. Sleeplessness was best met by veronal or trional. With regard to the serum treatment, there was no evidence of any good result. The vaccine treatment was more encouraging, but there was much work to be done before any definite conclusion could be reached.—The paper was discussed by the President, Dr. B. Baker, Mr. E J. Pritchard, Dr. E. C. Lambert, Dr. M. Mackintosh, and Mr. T. A. Howell.

MEDICO-LEGAL SOCIETY.—A meeting of this society was held on Dec. 17th, 1907, Mr. Justice Walton, the President, being in the chair.—Dr. W. A. Brand showed to the meeting a "Bill of Mortality," dated 1800, which referred to the number of deaths which had occurred in the various London districts for one week.—The President referred to the fact that 23 executions were chronicled but the burials of only 11 were recorded, the probability being that the other bodies were sent to the anatomy schools.—Mr. E. J. Blackett read a note on a case of Drowning of a Newly-born Child, and Mr. D. Cotes-Preedy brought to the notice of the meeting a case of manslaughter tried at the last Stafford summer assizes, the deceased's death following a fracture of the thyroid cartilage. —Dr. T. Claye Shaw read an interesting paper on the Radical Cure: Certification of Inebriates.—In the discussion that followed Dr. F. W. Mott, Dr. Charles A. Mercier, Dr. F. J. Smith, Dr. James Scott, Dr. W. Scott Tebb, and the President took part.—The President remarked that no judge with experience of criminal work could be of any other opinion than that so far as crimes of violence were concerned drink was generally the cause. As to whether drunkenness led to crimes of dishonesty his impression was that it was not the primary cause but that drink prevented efforts of reclamation. Dr. Claye Shaw seemed to have found fault with the criminal law, but he (the President) felt sure that the criminal law would never deal with inebriates as inebriates. The criminal law of this country did not punish habits but only specific acts.

Reviews and Notices of Books.

A System of Medicine by Many Writers. Edited by THOMAS CLIFFORD ALLBUTT, M.A., M.D. Cantab., LL.D., D.Sc., F.R.C.P. Lond., F.R.S., F.L.S., F.S.A., Regius Professor of Physic in the University of Cambridge, &c.; and HUMPHRY DAVY ROLLESTON, M.A., M.D. Cantab., F.R.C.P. Lond., Physician to St. George's Hospital, &c. Vol. III. London: Macmillan and Co., Limited. 1907. Pp. 1040. Price 25*s*. net.

THE preface to this volume tells us that "as regards the more important articles [it] is a re-written rather than a revised successor of Vol. III. of the original edition" and such is indeed the case. In the opening article on Rheumatoid Arthritis Dr. A. E. Garrod now distinguishes two separate affections which he calls respectively rheumatoid arthritis and osteo-arthritis, a distinction which has recently been emphasised by the researches of a special committee at Cambridge. Spondylitis Deformans also receives separate consideration. The article on Gonorrhœal Rheumatism is now amplified into one on various infective lesions of joints, dysenteric, syphilitic, pneumococcal, and so forth. An article on Intermittent Hydrarthrosis is also new. Dr. H. Batty Shaw now writes on Pulmonary Osteo-arthropathy in place of Mr. A. A. Bowlby who is still, however, responsible for the sections dealing with Osteitis Deformans and Mollities Ossium. Dr. F. J. Poynton, who now assists Dr. W. B. Cheadle in the article on Rickets, contributes a new section on Achondroplasia which is illustrated by two good reproductions of photographs.

The article on Gout, written by the late Sir W. Roberts, is revised by Dr. J. Rose Bradford who gives some account of recent investigations on the purin bodies and their relation to the disease. We cannot help thinking that one or two graphic *formulæ* would have made this part of the subject clearer to those who have not specially studied the chemistry of these substances. Professor R. Saundby's article on Diabetes Mellitus is not much altered but the author now admits the possibility of a failure of the tissues to utilise sugar as part of the explanation of the condition, holding that "failure of the glycogen reservoir in the liver and reduction of the power of the tissues to consume sugar" together constitute "an adequate hypothesis of diabetes." The discussion of the relation of the pancreas to this malady is not very full and Cohnheim's hypothesis as to the interaction of the pancreas and the muscles is not mentioned. Dr. Rose Bradford is responsible for the section dealing with Diabetes Insipidus and apparently favours a nervous theory of the condition. Meyer's views as to the inability of the kidneys to excrete the salts of the blood except in extreme dilution (hyposthenuria) are not apparently thought worthy of notice. The senior editor's contributions on Sea-sickness and Mountain-sickness are now transferred to the division embracing General Diseases of Obscure Origin, where they are better situated than among ailments of the alimentary canal. Diseases of the Mouth are now intrusted to Mr. Walter G. Spencer, while the most noteworthy alterations in the division dealing with diseases of the alimentary canal arise from the division, among other contributors, of the large proportion of work originally allotted to Sir Frederick Treves. Thus the subject of Enteroptosis, now disfigured by the name of visceroptosis, a barbarous hybrid term, is dealt with by Dr. A. Keith, while Appendicitis—this name having prevailed over the more correct perityphlitis—is intrusted to Mr. C. B. Lockwood, whose article is full of excellent matter if the style is not quite equal to that of his predecessor. Intestinal Obstruction is fully dealt with by Mr. H. L. Barnard, and Acute Peritonitis, as well as other affections of the peritoneum, is in the hands of Sir W. H. Allchin. A new section on Shock has been contributed by Dr. T. G. Brodie; this condition is looked upon by the author as one of depression of the nervous centres. We are not quite sure of his meaning when he attributes this to "an *inchoate* and excessive series of impulses" (the italics are *ours*) which act on many parts of the cord simultaneously. The late Dr. W. S. Playfair's article on Diagnosis of Abdominal Conditions from a Gynæcological Standpoint is omitted in the present edition, presumably as being more suited to the companion volume edited by Professor Allbutt, with the assistance of Dr. T. W. Eden. Lardaceous Disease is also treated of elsewhere in the present edition. The section on Diseases of the Anus and Rectum, originally written by the late Mr. Herbert Allingham, has been revised by Mr. J. P. Lockhart Mummery who has added some coloured illustrations of appearances seen through the sigmoidoscope. The late Dr. Dreschfeld's revision of his articles on Gastric and Duodenal Ulcer was fortunately finished by the author before his death and these represent perhaps the last contributions made to medical literature by this distinguished physician. New sections which deserve notice are that on Congenital Hypertrophy of the Pylorus, written by Dr. G. F. Still, and that on Subphrenic and other forms of Peritoneal Abscess from the pen of Dr. T. D. Acland, which replaces the original contribution of Dr. Lee Dickinson.

The present volume well maintains the credit gained by those which have previously appeared and there is every indication that the new "System" will retain the place secured by the former edition as the most popular standard medical text-book in this country. Its 1040 pages are packed into a book of convenient size for reading, while the printing is excellent and singularly free from typographical errors. We are inclined to think that a rather more liberal allowance of illustrations would be an advantage but can understand the editor's reluctance to sacrifice more space in view of the expansion which ten years' increase of knowledge has necessitated in the total bulk of the work.

A Text-book of Embryology for Students of Medicine. By J. C. HEISLER, M.D., Professor of Anatomy in the Medico-Chirurgical College, Philadelphia. With 212 illustrations, 32 of them in colours. Third edition. London and Philadelphia: W. B. Saunders Company. 1907. Pp. 432. Price 13*s*. net.

THE first edition of this work appeared in 1899 and this may partly account for the following remarkable statement: "Prior to the beginning of the present century, little or nothing was definitely known concerning reproduction and development." Obviously the author has not revised this statement since the end of last century. The work is a plain, straightforward account of embryology—not in its widest sense but rather of *human* embryology. Very few authorities are cited and references to literature are practically absent. The sources of the borrowed illustrations—which are numerous, from the works of His, Bonnet, and others—are duly acknowledged. Here and there certain facts of comparative embryology are given but the work is essentially one on human embryology adapted for students. The author follows the natural order in his treatment of the subject, beginning with the sexual elements and their physiology and passing on to segmentation of the ovum, germ layers, and the beginning differentiation of the embryo, the formation of the body wall, intestinal canal, and the fœtal membranes, placenta, and umbilical cord. Then there is the more detailed description of the development of the external form of the body, its connective tissues and lymphatic system; and subsequently there is set forth the story of the development of the face and mouth, the vascular, digestive, respiratory, genito-urinary, cutaneous, nervous, and muscular systems; and lastly, the development of the skeleton and limbs. With His he takes three stages of intra-uterine development—the stage of the "ovum," then that of the "embryo," beginning at about the fourteenth day; the events from day to day are traced but the fourth week marks the most active growth of the embryo; and finally, the stage of the "fœtus," which comprises the time between the beginning of the second month and the end of pregnancy. The events that make up this period are described in order. The descriptions of development of the various organs are clear and not too long. Though the skeleton is taken last, and although it is the framework of the body in the anatomical or mechanical sense, it is not so embryologically. Its development is not begun, at least, not to any important extent, until all the principal organs are well differentiated, and its growth is largely subsidiary to that of the structure which it supports and protects; hence the story of its development naturally comes in at the end.

There is an elaborate tabulated chronology of development running to several pages, setting forth in parallel columns the chief events in the development of the human embryo from week to week and month to month. The work is, as we have already said, a plain, straightforward account of the human embryology for students of medicine rather than for those studying embryology from the point of view of science.

The Nervous System of Vertebrates. By J. B. JOHNSTON, Ph.D., Professor of Zoology in West Virginia University. With 108 illustrations. London: John Murray. 1907. Pp. 370. Price 15*s.* net.

THIS work deals with the nervous system from a broad point of view and endeavours, we think successfully and succinctly, to trace its phylogenetic history and to show the factors which have determined the course of its evolution. More especially is attention given to its functional relations. There is little of mere descriptive anatomy. The account of the phylogeny of the forebrain differs from that usually given, while the statement is made that the taste buds are developed in the entodermal lining of the pharynx. If this be so it establishes an exception to the statement that all nervous structures are derived from the ectoderm.

The work is set forth under the following heads: general morphology, development, nerve elements and their functions, and the functional divisions, including the somatic afferent division, the visceral afferent division, general and special, and the somatic motor and visceral efferent divisions of the nervous system. Then follow a chapter on the sympathetic system and others on centres of correlation and the cerebellum, the evolution of the cerebral hemispheres, and the neopallium.

The short description of the general morphology is excellent and the account of brains in fishes is suggestive. The chapter on development forms a natural and excellent corollary to the foregoing. As to the importance of cephalisation this has brought with it, or rather the process consists in the development of, special sense organs, consequent enlargement of the brain and the formation of a rigid cranium to protect these organs, the disappearance of certain muscle segments and a change in position and functions of other muscles—e.g., eye muscles, the reduction in the number of gills, and with this the disappearance of various nerves and somites, the shifting of position of various organs and nerve roots due to these changes, and, lastly, the great development of the higher centres. The experiment of Bethe on the nerve cells of the crab Carcinus seems to show that nerve impulses can pass through the processes of a nerve cell without traversing the body of the cell itself. There is a careful but not captious analysis of the neuron theory and it is now admitted that the part of this theory which treats of the doctrine of contiguity is definitely disproved. The nervous system as a whole may be considered as a complex of neurons variously linked together into functional systems, representing at once the mechanism by which certain work is done and a record of the experience of the individual and the race.

When treating of functional divisions of the nervous system the general plan of the body shows actions in relation to the external world and those related to internal activities having to do with the processes of nutrition and reproduction—i.e., somatic and visceral. This scheme is admirably set forth and worked out in the brain of selachians and in man. In fact, these chapters are amongst the best in the book Anyone making a careful study of these systems—afferent and efferent—as set forth by Professor Johnston will find new light on the complex problems and cumbrous nomenclature of the mammalian brain. The cutaneous division, with the special sense organs in fishes and the differentiation of cutaneous and auditory centres and the cerebellum, are well worked out, and this is the case also with regard to the study of the visual apparatus and visceral system and its components. The description of the development and evolution of the sympathetic system is compactly set forth and the same may be said of the cerebellum, and here we may point out the fallacy of the statement that the cerebellar hemispheres of mammals are new formations not found in submammalian classes. The hemispheres are formed first. The evolution of the cerebral hemispheres is made plain and interesting. In connexion with the study of the neopallium the work of Golgi, Cajal, and Flechsig naturally is largely drawn on. There are references to literature at the end of each chapter and also short notes on laboratory work. The book is such as could only be written by a skilled zoologist. It contains many original observations. We strongly commend it to the study of the younger zoologists and neurologists.

Studies in Laboratory Work. By C. W. DANIELS, M.B. Cantab., and A. T. STANTON, M.D. Tor. Second edition. London: John Bale, Sons, and Danielsson, Limited. 1907. Pp. 491. Price 16*s.* net.

A NEW edition of this excellent work for research in tropical diseases has been necessitated by the rapid advances which have been made in all branches of tropical medicine since the first was published. These advances have in the volume before us been considered and especially information as to the known carriers of disease has been added, including ticks, biting flies, and fleas. Dr. Daniels also has had the advantage of the coöperation of Dr. Stanton in the preparation of the volume; the result has been to furnish the student of tropical medicine with a work thoroughly up to date.

In their opening chapter the authors show how the medical man practising in the tropics can best cope with the disadvantages entailed by the absence of the well-equipped laboratory which is usually found in European institutions. An excellent chapter then follows with reference to post-mortem examinations, the statements contained therein being only too familiar to those who have had experience in the deadhouse in the tropics. The all-important subject of the examination of the blood is next considered; the different varieties of the corpuscles are described, as well as the methods of making blood films and the various particulars as regards staining. The succeeding four chapters deal with the question of the parasites found in the blood and here the student will find a very complete account of the organisms of malaria. The Leishman-Donovan bodies receive due attention, as do also the filariæ. Certain properties of blood plasma and blood serum are then considered; here Sir A. E. Wright's theory of opsonins finds due expression. The authors give a brief but quite satisfactory account of the blood-sucking flies, mosquitoes, ticks, and fleas, illustrated by some excellent drawings. The student of the subjects connected with malaria and yellow fever is taught how to dissect mosquitoes, whilst the eggs, larvæ, and pupæ and their breeding places are demonstrated. Fleas, lice, bed bugs, and ticks are classified and described, after which the pigments and various forms of degeneration found in the tissues are dealt with. The subject of the parasites is finally concluded by an account of their presence in the tissues.

The important subject of the fæces is considered and the various points requiring observation are laid down; the method of examination of the various parasites contained therein is demonstrated. The chapter would, however, have been rendered more complete had the method of washing the dysenteric stools as laid down by the late Dr. E. Goodeve been mentioned, for by this method the observer is enabled to determine better than by any other with which we are acquainted the condition of the affected bowel and the prognosis that should be formed concerning the outcome of the disease. After that of the fæces comes the examination of the urine in which we note mention of Cammidge's researches. The volume concludes with the subject of bacteriology as practised in the tropics. Here the difficulties of the subject as experienced in these conditions are noted and an excellent table is given of the organisms of special interest as regards tropical countries. The last two chapters are occupied with the questions of measurements of the various eggs, parasites, and normal and abnormal cells, and with that of statistics in the tropics.

The authors have placed at the disposal of the student of tropical medicine a mine of information without which he cannot be considered properly equipped.

The Röntgen Rays in Medical Work. By DAVID WALSH, M.D. Edin., Senior Physician, Western Skin Hospital, London. Fourth edition. London: Baillière, Tindall, and Cox. 1907. Pp. 433. Price 15*s.* net.

THIS work was one of the first, if not the first, of its kind to be published in this country, and that its publication was justified is well shown by the issue of a fourth edition. The general arrangement of the work is essentially the same as before. The first part dealing with apparatus has been again written, or rather rewritten, by Dr. H. Lewis Jones. All the essential details are fully gone into and it is refreshing to observe that the usual "padding," consisting of one or more chapters on elementary electrical physics, so commonly found in works of this kind, has been omitted. The second and major part of the work is devoted to the application of the x rays in medicine and surgery. The localisation of foreign bodies in both civil and military practice comes in for a very full share of attention and here, as in the other parts of the book, we note the superior character of the illustrations which go so far to elucidate a subject of this kind. Those prepared from radiographs by Dr. David Morgan of Liverpool are worthy of special mention. In the purely medical section the author rightly insists on the great and valuable help which this agent is capable of giving in the diagnosis of thoracic disease. From an almost daily experience of the method we can bear testimony to its value; and the facility and speed with which an otherwise doubtful point can be satisfactorily settled are sufficient to impress the most sceptical. The closing chapters are devoted to legal medicine, anatomy, and physiology. We can confidently recommend the volume to all those who are interested in x ray work of any kind.

Post-mortem Pathology: A Manual of the Technic of Post-mortem Examinations and the Interpretations to be Drawn Therefrom. By HENRY W. CATTELL, A.M., M.D., sometime Pathologist to the Philadelphia, Presbyterian, and Pennsylvania Hospitals. Third edition, copiously illustrated with coloured plates and figures. London and Philadelphia: J. B. Lippincott Company. 1906. Pp. 547. Price 18*s.* net.

THE third edition of Dr. Cattell's book has been enlarged and very considerably improved. In our review of the first edition we commended the practical character of the work as a handbook for the post-mortem room but pointed out that the descriptions of morbid conditions were meagre and incomplete and that the literary style was marred by the abrupt and unfinished character of many of the sentences. In this edition we are glad to see these defects remedied. The description of the methods of post-mortem examination and the general account of the technique of the examinations, of the dissections necessary to expose various organs, and of the methods of section remain as before thoroughly practical, clear, and easy to follow. The copious illustrations, which are mostly reproductions from photographs, contribute in no small degree to the value of the book. Careful general descriptions of the manner of using the various instruments are included and many practical hints are given. Where various methods are in use for the examination of special regions Dr. Cattell is careful to describe them in detail and to indicate those which in his own extensive experience have given the best results or to point out the value attaching to each for any particular purpose.

Among the chapters of special merit we may mention those devoted to the examination of the skull and the brain and to the investigation of the naso-pharynx, the eyes, and the ears. The descriptions of diseased conditions and morbid organs have all been considerably extended and improved, while a great deal of recent work has been incorporated in a form convenient for reference. The directions given for the preservation of tissues and for the bacteriological investigation of post-mortem tissues are succinct and thoroughly useful. A chapter on post-mortem examinations of the newly born contains valuable information on the subject and like all those referring to matters of technique is copiously illustrated, while the sections devoted to restricted post-mortem examinations and to the restoration and preservation of the body afford highly useful accounts of those subjects, containing a great deal of practical advice. A section on weights and measurements given in English and metric figures leaves nothing to be desired, while that devoted to post-mortem examination of the lower animals gives a few general hints in regard to their performance in such mammals as the horse, ox, sheep, and dog, and also in birds. A very brief chapter on plant pathology is perhaps hardly necessary, as it includes but little of practical importance, although various suggestive lines of research are indicated. A long chapter headed "medico-legal suggestions" we have read with interest, since it incorporates a considerable amount of the author's personal experience as "coroner's physician" in Philadelphia.

Many useful references are appended to the text and it is a pleasure to recommend this book in its improved form as a valuable handbook for the student in the post-mortem room, or for the practitioner who is called upon to perform examinations of the dead body for medico-legal or other purposes.

Manuel Pratique de Massage et de la Gymnastique Médical Suédoise. (Practical Manual of Massage and of Swedish Medical Exercises.) By J. E. MARFORT. Third edition. with 111 figures in the text. Paris: Vigot Frères. 1907. Pp. 319. Price 5 francs.

A WELL-ILLUSTRATED handbook which shall be at once intelligible and of moderate size, describing in simple terms the general methods employed in massage and in the various forms of exercises adapted to medical purposes, is likely to serve a useful purpose. The small book before us fulfils most of these requirements; it is well written, abundantly and clearly illustrated, and is of convenient size. Though not a medical practitioner, the author has a general acquaintance with the anatomical and physiological facts necessary for a proper appreciation of the principles underlying the therapeutic application of massage and muscular exercises. Indeed, he strongly emphasises the necessity for adequate and sufficient training in the theory and practice of these methods, and declaims against the harmfulness likely to result from the application of them by those with but a few weeks or months of training. He points out that in Sweden a course of three years at the Royal Institute of Massage is necessary before a diploma is granted. He insists on the importance of the application of these therapeutic methods under medical supervision by skilled persons and refers to various injurious effects which may be induced by their injudicious application.

The first section of the book opens with a chapter on the history of massage and of its recent developments and applications; another follows on general considerations relating to the uses and applications of massage and muscular exercises. The second part of the book deals with the technique of massage. The various processes of *effleurage, écrasement, pétrissage, tapotement, ondulations,* and *vibrations* are outlined and very clear figures are given in illustration. Various mechanical vibrators are described, including one devised by the author. The application of massage to the body generally and to the various organs is next discussed and the position of the patient and the operator is clearly defined. In this section it seems to us that unnecessary importance has been given to massage in gynæcological conditions.

The third section of the book is devoted to medical gymnastics and in it the passive and active movements applied to the various muscular groups are described and illustrated by figures or diagrams. In connexion with the active movements the various respiratory exercises are given. In this section certain resistance movements are noted such as those recommended in the treatment of some forms of cardiac disease. The exercises used in the treatment of scoliosis are also described and figured.

The fourth and concluding section of the work deals with the physiological actions of massage and of muscular movements and with the indications for their use in practice. This would have been more suitably written by a medical author or in collaboration with one. It includes supposed indications for the application of these methods in a very great variety of conditions. None the less, as we have said at the outset, this is a practical and handy little book on the subject of which it treats.

LIBRARY TABLE.

Encyclopædia and Dictionary of Medicine and Surgery. Vol. VI., Lumbar Region to Nephrotomy. London and Edinburgh: William Green and Sons. Pp. 562. 1907. Price 15s. net.—The sixth volume of this valuable encyclopædia of medicine and surgery contains more subject headings than any previous volume with the exception of the second. The subject most extensively dealt with is that on Diseases of the Lungs, but besides this long article there are 48 others of more than 1000 words in length, as well as 82 of less than 1000 words and more than ten lines in length. The rest of the volume is made up of 1100 short paragraphs or definitions. Amongst the various subjects dealt with we find an able article on Lunacy by Dr. J. F. Sutherland, in which the practitioner will find information on all the chief points of the affections included under this term. Dr. R. W. Philip, Dr. S. H. Habershon, and Dr. R. A. Fleming contribute the excellent section on the Lungs. The historical aspect of tuberculosis is well drawn. This is followed by the section on the etiology, pathological anatomy, and symptoms. Then we come to an excellent exposition of the physical signs of the various stages. The clinical varieties and complications are detailed and are followed by the diagnosis, prognosis, and treatment. Much information is given about the sanatorium treatment. The remaining diseases of the lungs are dealt with in an equally explicit manner. Dr. Norman Walker contributes an excellent article on Lupus Erythematosus. In his opinion we note that internal medication is rarely of much value. This is not, however, by any means universally held, as the salicylates have been found by other authorities to confer much benefit on the sufferer from this affection. Dr. G. Lovell Gulland gives a valuable contribution on the Physiology and Pathology of the Lymphatic System. The tabular statement of the glands showing the source of their afferent vessels and the destination of their efferent vessels is concise and complete. This is followed by a description of the different diseases of the lymphatic glands and their treatment. The article on Malaria, perhaps the best in the volume, is contributed by Mr. D. O. Rees. This writer gives a succinct account of the various steps whereby the mosquito theory was finally established. He then describes the biology of the malarial organism and the life-history of this parasite, which is illustrated by some excellent plates; the different species of the mosquito receive attention together with the development of the malarial organism in these hosts. The student is taught how to demonstrate the parasite, after which the clinical features of malaria are described with the various sequelæ that may ensue. The sections on the morbid anatomy, the etiology, and the treatment, both curative and prophylactic, complete the article. Mr. T. D. Patmore writes exhaustively on the subject of malingering and gives many amusing instances of the manner in which malingerer were detected. Mr. H. J. Stiles discusses the Diseases of the Mammary Gland in an article which will well repay perusal; this also is illustrated by some excellent plates. Dr. F. de Havilland Hall contributes a lucid article on the Diseases of the Mediastinum, whilst Dr. A. Mackintosh, Dr. G. F. Still, and Professor W. Osler deal with the matters connected with the meninges, describing the anatomy, physiology, and vascular disorders of these membranes, and tuberculous, posterior basic, and epidemic, cerebro-spinal meningitis. Amongst the other sections in the volume may be mentioned that on the Injuries and Diseases of the Mouth and Jaws, by Mr. H. P. Dean; a very good article on Mycetoma, by Lieutenant-Colonel W. Keith Hatch; and lastly, an excellent contribution on Nephritis, by Dr. Nestor Tirard. This volume fully sustains the reputation of its predecessors.

Manual of Practical Anatomy. By D. J. CUNNINGHAM, M.D. Dub. and Edin., D.Sc., LL.D., D.C.L., F.R.S., Professor of Anatomy in the University of Edinburgh. Vols. I. and II. Fourth edition. London and Edinburgh: Young J. Pentland. 1907. Vol. I., pp. 621; *Vol. II.* pp. 600. Price 10s 6d per volume.—The appearance of a fourth edition of Professor Cunningham's well-known "Manual of Practical Anatomy," besides affording conclusive proof of its popularity also points to the characteristic thoroughness of the author in having once again brought his book up to date. The general plan of the work, which like its predecessors is still published in two volumes, remains unaltered but the text has been carefully revised and several parts, chiefly in the chapters relating to the abdomen and thorax, have been rewritten. A large number of new illustrations have likewise been added to both volumes. The figures depicting the right and left pleural chambers, as seen from the side after removal of the lungs and a portion of the chest wall, are particularly instructive and should be of great assistance to the student. In the section devoted to the heart the text is amplified by many excellent illustrations, one of which depicts the auriculo-ventricular bundle in the heart of a calf. The chapters on the head, neck, and brain are particularly good and leave nothing to be desired. No less than 30 new illustrations have been added to the second volume which deals with the limbs and abdomen, whilst the text in the latter section has been rewritten in many places. The account of the stomach, pyloric canal, and pyloric vestibule is very clearly given and is liberally illustrated. Though several pages are still devoted to the pelvic fascia we fear that the average student very seldom sees the many layers and ligaments which are so aptly described. Professor Cunningham's "Manual of Practical Anatomy" is undoubtedly the best work of its kind in the English language and thoroughly deserves all the success which it has gained.

The "Ideal" Medical Diary and Visiting List. London: Langley and Sons. Price 7*s.* 6*d.* in morocco cover; visiting list refills, 3*s.* 6*d.*; duplicate prescription refills (50), 6*d.*, or 5*s.* 6*d.* a dozen. *Wellcome's Medical Diary and Visiting List, 1908.*—We noticed the editions for 1907 of both these diaries fully in THE LANCET of Jan. 26th, 1907, p. 236. Similar diaries for 1908 have reached us in which the main features are repeated. The "Ideal" Diary is a neat and handy pocket-book and the removeable visiting list and blank prescription forms are distinctly serviceable. Messrs. Burroughs, Wellcome, and Co.'s Medical Diary and Visiting List is widely known and appreciated.

Walker's Diaries. London: John Walker and Co., Limited.—We have received a selection of pocket diaries from Messrs. Walker and Co. which are of the accustomed quality of their annual publications. Those before us are in various bindings and of different prices, from an "American Russian" one page at an opening at 3*s.* 6*d.*, to a tiny "quarterly" waist-coat-pocket diary with refills at 1*s.* Those with pigskin bindings are especially serviceable but all are well and neatly bound.

The Poetical Works of Thomas Campbell. Pp. 400. Price 2*s.* *The Poetical Works of Shelley.* Pp. 928. Price 2*s.* The Oxford Edition. Oxford: Henry Frowde. 1907.—The above-mentioned works are two more volumes of the admirable Oxford Edition of Poets, one volume of which—namely, the Keats—we reviewed recently. For one person who knows the works of Campbell probably 50 know those of Shelley, and although the former was not to be compared with the latter as a poet, yet some of his lyrics are among the finest things in the English language. The volume opens with "The Pleasures of Hope," a poem which is quite up to the standard of the average Newdigate, but which, like all eighteenth-century didactic poems, irresistibly reminds one who has read the poetry of the Anti-Jacobin of the famous "Loves of the Triangles." This, however, was a youthful flight. Campbell's real poetic genius is shown in "The Battle of the Baltic," in "Hohenlinden," in his songs, and above all in that magnificent poem, "The Last Man," with that wonderful couplet,—

> "And ships were drifting with the dead
> To shores where all was dumb."

Much may be forgiven to a man who could write like that, even

> "The sunset sheds a horizontal smile,"

as he wrote elsewhere. Mr. J. Logie Robertson supplies an introduction and notes. As regards the "Shelley," which is edited by Mr. Thomas Hutchinson, who writes an introduction, the reader finds here a complete collection of all the works of Shelley which have appeared in print hitherto, including fragments. The Oxford University Press deserves great credit for making it possible for those whose purse is not deep to possess well-printed, well-edited copies of imperishable literature.

The Explorer. By W. S. MAUGHAM. London: W. H. Heinemann. 1908. Pp. 297. Price 6*s.*—When we reviewed Mr. Maugham's first book, namely, "Liza of Lambeth," while giving him full credit for a clever book full of observation we ventured to hope that in future works he would choose a less sordid subject. This hope was fulfilled in a later book—"Mrs. Craddock"—and in the book now before us he has risen to a greater height still. "The Explorer" is a fine study of two fine characters and, as is always the case, they are refined by suffering. Alec MacKenzie is by no means perfect, he makes mistakes and profits by them, but his course is ever upward, and at the end we leave him strong in the love of the woman who is everything to him and happy in the consciousness that he will return from an expedition full of danger. The minor characters are well drawn and no one in the book bores the reader. Altogether, "The Explorer" is a book to be read and enjoyed.

JOURNALS AND MAGAZINES.

The Journal of Balneology and Climatology, October, 1907 (the official quarterly of the British Balneological and Climatological Society). This number contains Dr. Norman Moore's address on "Air, Water, and Sanitation," which has appeared *in our columns*; *some notes* on the Shropshire Highlands and the Westnor Saline Water, by Mr. Norman Hay Forbes; a paper on the Relation of Temperature, Humidity, and Winds to Chronic Nephritis, by Dr. W. R. F. Phillips; and a communication by Professor Victor Schmieden on Bier's Method of Treating Inflammations by Stasis and Hyperæmia, translated by Mr. Charles G. Levison of San Francisco. This is a very clear and able *summary* of the technique of applying Bier's treatment by bandaging or suction or heat to the various parts of the body. It is entirely practical and does not touch on the principle underlying a method which is proving increasingly useful. The translation is able but we must protest against the term "stased limb" used throughout for a limb undergoing venous stasis.

Proceedings of the Royal Society of Medicine, Vol. I., No. 1.—We have previously alluded to the *format* of the official journal of the Royal Society of Medicine,[1] which is edited by Dr. John Nachbar under the direction of an editorial committee representing the various sections of the society. The first number contains reports of the opening meetings of the various sections, including *presidential* addresses by Sir Thomas Barlow in the Clinical Section, a most interesting and stimulating review of the past work of the Clinical Society; by Dr. H. Radcliffe Crocker in the Dermatological Section; by Mr. W. Deane Butcher in the Electro-Therapeutical Section on the Future of *Electricity in* Medicine, a fascinating forecast which has already appeared in these columns; by Dr. A. Newsholme in the Epidemiological Section *on Poverty* and Disease as illustrated by the Course of Typhus Fever and Phthisis in Ireland, which is a very painstaking and exhaustive study; by Dr. Samuel J. Gee in the Medical Section; by Mr. J. Howard Mummery in the Odontological Section; by Mr. S. G. Shattock in the *Pathological* Section; and by Dr. T. E. Burton Brown in the Therapeutical and Pharmacological Section. The most noteworthy of the papers printed in the present "Proceedings" is probably that read by Professor E. Goldmann before the Surgical Section on "The Growth of Malignant Disease in Man and Lower Animals, with special reference to the Vascular System."[2] There is a large number of interesting cases recorded, with abstracts of discussions held on some of them, to which we need not further allude, as many of these cases have been recorded in our columns.

Reports and Analytical Records

FROM

THE LANCET LABORATORY.

SAUERIN.

(Allen and Hanburys, Limited, 37, Lombard-street, London, E.C.)

"Sauerin" is described as a pure culture of a vigorous strain of bacillus acidi lactici prepared in tablet form for internal use and for the production of soured or curdled milk. We owe to Metchnikoff and others the discovery that an active strain of lactic acid producing bacteria inhibits the growth of the bacillus coli communis and other intestinal bacteria in the colon by producing lactic acid. The suggestion, therefore, is that the active lactic acid producing bacillus might be given to act as a general intestinal disinfectant and might prove useful in disorders arising from a toxic process in which excessive intestinal putrefaction is involved. Already some evidence has been obtained that lactic acid is valuable in the direction indicated. We have submitted the sauerin tablets to experiment and have found that they are active in producing lactic acid readily when cultivated in milk kept at a blood temperature. The organisms, of course, attack the milk sugar, converting it into lactic acid. The milk so treated appears to present the lactic acid in a most active form for administration. The curdled milk can be flavoured with cinnamon, nutmeg, or other substance according to taste. The method suggested appears to be worthy of trial.

MARMITE (SAVOY BRAND).

(The Marmite Food Extract Co., Limited, Mincing-lane House, 59, Eastcheap, London, E.C.)

We have already submitted ordinary Marmite Food Extract to analysis, but we have recently received a sample known as the Savoy Brand which is stated to be obtained by submitting the ordinary marmite to an additional process whereby it becomes more highly refined and also retains the flavour of the fresh vegetables which are used in the process. The flavour, in our opinion, is certainly good and is barely distinguishable from good beef extract, yet marmite is entirely of vegetable origin. Our analysis, which practically agrees with an analysis a copy of which has been sent to us, gave the following results: moisture, 23·84 per cent.; mineral matters, 19·78 per cent.; and extractives, 56·38 per cent. The extractives include over 2 per cent. of peptones and albumose, but for the most part the nitrogenous matters consist of bases, while the non-nitrogenous matters include lactic acid. The total nitrogen was 5·82 per cent. The preparation serves the purpose of a stimulant in much the same way as does meat extract, while it also contains a definite proportion of real nutritives.

COGNAC BRANDIES.

(De Laage Fils and Co., Cognac. London Agency: Noakes and Co., Limited, White's Grounds, Bermondsey, S.E.)

Of the two samples of brandy submitted to us one was described as "three stars" and the other as 25 years old. Our analysis, especially in regard to secondary products, gave results identical with those given by genuine Cognac brandy. The ethers in both instances amounted to 100 parts per hectolitre, the furfural amounted to 1 part, and the higher alcohols to just short of 200 parts. The 25 year old brandy was more elegant in regard to taste and bouquet than was the "three stars." It was, however, somewhat sweet to the taste. There is no evidence on analytical premisses that these brandies are not the genuine products of the Cognac district. They contain a notable amount of extractives and resinous matters derived probably from storage in wood.

SARDINES (CROSSED FISH BRAND).

(Stavanger Preserving Company, Norway, and Coronation House, 4, Lloyd's Avenue, London, E.C.)

The sardine preserved in olive oil fills an important place in the dietary, since not only is it appetising but decidedly nutritious also. The Norwegian sardine is further submitted to a process of smoking which, in the view of many, adds considerably to its palatable qualities. The sardines at any rate of the above company are very agreeable to the palate and, so far as we can see, are prepared with care. We could find no evidence of metallic contamination either in the olive oil or in the fish. There was just a slight indication that the sardines prepared with tomato purée contained a trace of metal. This could be avoided by using varnished or lacquered metal when it is intended to pack the fish with an acid-containing substance such as is the pulp of the tomato.

JAMAICA TEA.

(The Colonial Planters, 154, Church-road, Hove, Sussex.)

In our recent articles on Jamaica as a Health Resort we have alluded to the production of tea in that colony. We have since had the opportunity of submitting a sample to analysis, with the following results: moisture, 7·60 per cent.; mineral matter, 5·50 per cent.; tannin, 8·22 per cent.; and theine, 1·60 per cent. According to this analysis it is worthy of note that the tannin is decidedly less than that contained in either China or Indian tea, the average amount being 10 per cent. The theine, however, occurs also in smaller quantity in Jamaica tea but this may not be a disadvantage. The flavour of the tea is decidedly delicate, being free from the roughness of coarse teas; it is, however, not so attractive to the palate as that of fine oriental teas.

PATENT COVERED COOKED HAM.

(Walter Mitchell and Sons, Ayr.)

We have received a cooked ham from which the bones have been removed, contained in a stout gelatin corton. The meat proved to be quite sound and it is said that this method of packing keeps it sound for months. The hams, we understand, have been supplied to the Royal Navy. We quite admit that this cover is an improvement on the tinning method provided that it protects the meat from undesirable changes. We found that the gelatin corton was impregnated with boric acid. The corton is known as the gelantiseptic cover.

SOLOID BLACK MERCURIAL LOTION.

(Burroughs, Wellcome, and Co., Snow Hill Buildings, London, E.C.)

This soloid is convenient for readily obtaining the black mercurial wash of the pharmacopœia. One soloid powdered and shaken with one fluid ounce of water gives a lotion containing the same mercurial equivalent as the lotio hydrargyri nigra. By adding 24 minims of glycerine to the fluid ounce the official preparation is more nearly represented, glycerine serving to prevent the black suboxide of mercury produced by the inter action of the lime and calomel from oxidising to yellow mercuric oxide.

New Inventions.

MELVIN'S PORTABLE "SANATORIUM."

The illustration depicts a portable hut designed and patented by Mr. Melvin of Glasgow. The floor, sides, ends, and roof are made of a strong wooden framework, the floor being covered with match boarding. All the parts are hinged in the centre, so that they can be folded and thus rendered easy to transport. The sides, ends, and roof are covered with a specially prepared waterproof canvas. The sides and ends are attached to the floor and to each other at the four corners by thumb-screws and sockets. The thumb-screws can be unscrewed sufficiently far to release them from the sockets but cannot be entirely removed, thus obviating the danger of loss. The door and the two windows are hung on loose pin hinges and may be lifted off and hung, opened, and closed at will. The means for ventilation are good. The beds used in these huts are fixed somewhat after the manner of those in a ship's cabin and can be easily placed in position and taken down. The table, the hat and coat hooks, and other furniture are also designed so that they can be removed without difficulty. The sanatorium which we saw was 8 feet 6 inches in length and 6 feet 3 inches in width. When packed it occupied a space of 50 cubic feet and weighed three hundredweights. The advantages claimed for these huts over the ordinary huts or tents are that they are comfortable, they can be placed in position and taken down in a few minutes, and they are storm proof and well lighted and ventilated. The uses to which such buildings could be put are many and medical men will hardly require to have them pointed out. The London and export agents are Messrs. Strachan, Turner, and Co, 37, Lime-street, London, E.C., from whom all particulars may be obtained.

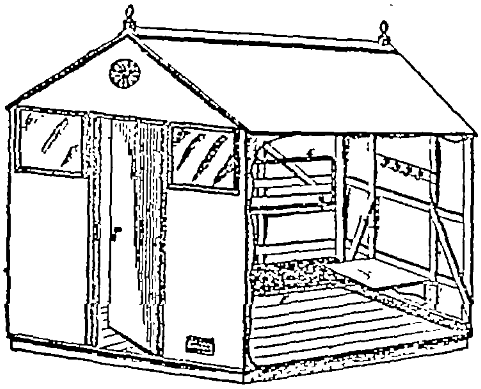
[2] The Lancet, Nov. 2nd, 1907, p. 1236.



Looking Back.

FROM

THE LANCET, *SATURDAY*, Jan. 2nd, 1830.

I received some of my medical education at Guy's Hospital;[1] and at the time I was a pupil there, Dr. James Curry, knowing the important share the liver had in *disease*, and the great use of mercury, rendered me an essential service by much that he taught; though for the liver, I now know that we ought to substitute *the whole order of hepatic*, gastric, and intestinal organs; yet, to so absurd a pitch would he carry his views of the importance of the liver, that he would have had one believe that, in all diseases, the liver was importantly affected, and that the chief attention ought to be paid to it. I once saw a case of urethral stricture relieved by the warm-bath; and in which, he said, the relief was obtained through the warm-bath relaxing the biliary ducts, and that the stricture in the urethra became relaxed, merely by sympathy with their relaxation. The practice now so strongly recommended by Broussais in France, of withdrawing blood from the abdomen in fever, was always strongly inculcated by him; to me, Broussais's practice offers nothing new; it is what, owing to the instructions of Dr. Curry, I have all my life adopted; that is to say, I always looked out for abdominal tenderness, and remedied it by local bleeding. Dr. Curry's error was, in contending that the liver was so peculiarly affected in fever, that the tenderness all around the region of the liver, was to be attributed entirely to disease of that organ; whereas, it is the stomach and intestines, at least as much as the liver, that suffer. On his absurdity in mercurialising *for every disease*, as he positively did, I need not dwell. A surgeon, now retired from practice, saw, better than his surgical brethren, the utility of blue pill, and the importance of attending to the stomach and bowels; but he was not content with exhibiting it where it was improperly neglected by other surgeons; he gave it indiscriminately in any case, *medical or surgical*, and would generally not take the trouble to investigate a case, or even to look at a local affection, but at once called out, "The stomach, the bowels, are in fault, and blue pill must be taken;" so that with him, I have no hesitation in saying, as Dr. Macculloch does, at p. 55, that this was "an abuse, convenient to indolence, by superseding the necessity of thought or investigation, and by reducing the whole practice of physic to an empiricism, to which I know not that its entire history can produce a parallel example." "If the united ignorance and presumption," Dr. Macculloch goes on to say, at page 162, "of self empirics could ever find an excuse, they might, indeed, claim it in this case, when they see practitioners *of high fame*, if notoriety be fame, following similar universal systems of cure, applying salts, or the blue pill, to every disorder or symptom in the nosology, and without inquiry; and thus, while saving themselves all the trouble of thinking, rendering physic an art, which may be practised by any one without previous study, or present observation." So great has been this influence upon the public, this infatuation, that in England, *few persons are now contented, when requiring a plain* laxative, with the mild vegetable aperients, which we have in abundance, and which produce no constitutional effects, but merely open the *bowels; every one must take a portion* of blue pill, of a metal which does more than is required for habitual use; which weakens the stomach and whole frame, and gives a susceptibility of cold. Zimmerman, in his work on experience, page 140, notices this tendency in our profession to *patronise* particular organs, or diseases, or remedies. "I know," says he, "several physicians who see only certain diseases: one of these, who is a *celebrated practitioner*, and *who has an obstructed* liver, fancies he discovers a similar complaint in all his patients, and it is one particular remedy he constantly prescribes, because he finds it useful to himself; another is in love with his theriaca, probably because it confines him to his bed, sometimes for three months; without this same theriaca, if we are to believe him, he would long ago have been overcome by his complaints; but with this, says he, I can master them. I know a third, who is confined three or four months every year with the gout, and yet he constantly denies that he has anything gouty about him, and contends upon all occasions that he never had so much as the rheumatism. This physician, and all his patients about him, if we are to believe him, are subject to an affection of the nervous system, and he employs narcotics upon all occasions." The very same things are said in rhyme by our own poet Crabbe:—

> "*One to the gout contracts* all human pain,
> He views it raging in the frantic brain;
> Finds it in *fevers*, all his *efforts* mar,
> And sees it lurking in the cold catarrh.
> Bilious by some, by others nervous seen,
> Rage the fantastic demons of the spleen;
> And every symptom of the strange disease,
> With every system of the sage agrees."

Moliere, in his *Malade Imaginaire*, in the person of a sham physician, who *patronises* the lungs, ridicules this propensity, and as each symptom is mentioned by the unhappy patient, *nods his head and says*, "*Le poumon! justement le poumon!*" and when the patient has finished, exclaims "*Le poumon! le poumon!!*" Some, struck with the fact, *that inflammation attends so many* cases of so many diseases, consider every disease an inflammation, as though this explained the phenomena of tubercles, cysts, cancer, melanosis, dyspepsia, diabetes, and every thing else. The occurrence of inflammation in so many affections, is sometimes the *disease itself*; *sometimes an exciting cause*, sometimes a concomitant, sometimes a part only of the disease, sometimes absolutely an effect, and, in a large number, it is really absent. No one is more aware than myself, of the importance of looking out for inflammation in every case, and of treating it *if found*; *but this supposition* of its universal existence, and of its universality as a cause of disease, is a mere assumption. My convictions from close, I may say painful *observation* and reflection, are the same as those of Dr. Andral, in his recent work on morbid anatomy; a work which shows full information, and a solid and dispassionate judgment, and is the production of a man who one day or other, I am sure, will be the first physician in France.

---

[1] Excerpt from "Clinical Lecture by Dr. Elliotson, delivered at St. Thomas's Hospital. Fever."

THE LANCET.

LONDON: SATURDAY, JANUARY 4, 1908.

The Diffusion of Medical Knowledge.

DURING 1908 THE LANCET will enter upon the eighty-sixth year of its existence,[1] and while the beginning of every new year is naturally made a season for moralising we hope that we may claim indulgence for a few words of self-congratulation. We are not blind to the need for moralising or unaware that during our career we must have made errors, but at any rate we can claim that we have never faltered in our long endeavour to maintain the dignity of medicine and the rights of the medical practitioner. This was the object with which THE LANCET was founded, and the purpose of the founder has been carried out steadily by his descendants, the eldest of whom death removed from the editorial chair during the year which has just ceased. We shall deeply miss his counsel and the lessons of his experience, but we commence the new year with confidence, for we possess the reassuring knowledge that we shall have extended to us by our professional brethren the same steady support that we have received without intermission from the inception of the journal. We have come to perceive that the work of THE LANCET is considered by the medical profession to be in its nature coöperative, and year by year we are confirmed in this flattering view. We can only give to our readers the latest medical learning and the most practical professional information if we in our turn are helped by our readers. Our editorial efforts would have no practical result if we did not find among our public many who are anxious to communicate through us with their professional brethren, thus rendering our pages a central bureau for the collection and redistribution of knowledge. The responsibilities which are thus placed upon us grow no lighter with experience in the attempt to meet them. On the contrary the progress of scientific medicine brings with it every day fresh problems; something new occurs incessantly which may or may not be significant of an important development. Fortunately it does not depend upon ourselves alone to decide in all instances what movements make for truth and what are based upon error. Our duty is to hear all sides and by submitting them to the judgment of our readers to obtain the assistance of their criticism before making any pronouncement. We trust also that we shall not be found afraid to lead when initiative is required.

It seems to us that the feature which has most prominently marked our columns during the past five years is the desire of medical men in all parts of the world to communicate with their fellows. It is a truism, which may be found in our columns as well as in those of every scientific newspaper in every language, that science has no geographical limits any more than it has political bearings. It is, or should be, as absurd to talk of a French school of medicine or a British school of gynæcology as it would be to talk of a Home Rule system of dentistry. There is scientific medicine, scientific gynæcology, and scientific dentistry, and in each case the essential doctrines must be dictated by knowledge of the truth, by adaptation of accepted principles to circumstances, and by examination and sifting of scattered facts so as to form them, through collation and comparison, into the foundations of a theory. When, however, we pass from the theory to the practice of medicine it is obvious that the environments of practice will have much to say in respect to the measures employed as well as to the conditions observed. The climate, the health and the manners of the people, the extent to which they are as a whole liberally educated or the reverse, the industries on which the population is employed, the ease or difficulty with which money is gained at those industries, and all the other circumstances which make up the sociology of a race will, of course, determine the classes of disease and of injury which are likely to be prevalent, as well as the facility or difficulty with which remedial actions may be taken. But the methods of diagnosis must be universal and those of treatment must be based upon identical and ascertained truths. When the world was small and the interchange of ideas between distant nations was restricted owing to the rigorous limitations of the means of transport, although the scientific practice of medicine was bound to have the same foundations all the world over, the conditions were such that in different places different procedures were pursued, for opportunities were wanting by which schools of thought could compare and test their theories and their results. But of recent years the association between the peoples of the earth has become vastly more intimate, and nothing so marks the progress of civilisation as this opening up of rapid channels of intercommunication. Great Britain and her colonies have gained a knowledge of each other during the short period which the twentieth century has yet run which is surprisingly large and general, considering that in the Victorian era most of those at home knew nothing of the life of our dependencies, while our colonial brethren knew but little more of us. This is a situation which has recently undergone satisfactory change. The United States of America in circumstances which have not been entirely cheerful for them have also improved their acquaintance with the rest of the world; they have learned something of the burdens which must be taken up by great civilising powers. On the continent the commercial industry of Germany has compelled all European powers to consider their fiscal position, with the result that there is a great increase on all sides of national knowledge of the trade-manners and trade-customs of foreign neighbours. Russia and Japan understand each other far better than they did before their terrific struggle and have learned lessons from each other which neither can ever forget. In a happier way the personal influence of our King has been used to secure a better comprehension of English aims by the world at large. The outcome of all this must be the placing of our profession upon a securer basis, for as the different nations rise in the scale of civilisation and obtain a more just acquaintance with their neighbours they must come to perceive how universal are the laws of scientific medicine. They find themselves confronted with the same problems, sanitary or pathological, as their friends abroad, and they learn to appreciate the labours of medical men by applying to their own use the fruit of these labours.

---

[1] The first number of THE LANCET was issued on Sunday, Oct. 5th, 1823. Consequently on Oct. 4th, 1907, it completed the eighty-fourth year of its existence, and upon Saturday, Oct. 5th, 1907, entered upon its eighty-fifth. It is obvious that it is not possible to make the age of THE LANCET tally with the calendar year. For purposes of convenience it is found to be most suitable to give upon the title-page of each volume of THE LANCET the year of existence entered upon in the course of that particular calendar year.

We have endeavoured, particularly during the last three or four years, to illustrate the truth of this movement by placing before our readers regular correspondence from all parts of the world. The mere size of such a programme makes it inevitable that the communications should be brief, but we are happy to know that they prove of considerable service to our readers, while it is interesting to observe how the same scientific and professional difficulties present themselves in every quarter. We hope and believe that in the newer countries scientific medicine will be able to develop faster than it has done in Europe in bygone days, for these countries will be unhampered by traditions having their origin in restricted knowledge and sociological misconception. In particular their authorities and important persons, both medical and lay, are able to work at once from a position to which we in this country are now only beginning to attain. They follow the reasons for scientific proceedings in a way which they could not possibly have done had it not been for the past labours of the medical profession; and the medical profession will be invited to call upon the assistance of laymen for the advancement of scientific medicine, a fact which is of great importance now that medicine touches the borders or passes over into the territory of so many other sciences. Great advances in medical knowledge are inevitably coming of the growing recognition of medicine by the world as a science compounded of sciences; while the disappearance from the popular mind of the conception of the practitioner as a sort of magician is being replaced in every direction by a more reasonable estimate of his services. We know —none better—that the practitioner has many drawbacks in his hard and anxious life, and we grieve to think that many of these could easily be set right in our own country by a more complete understanding of professional aims and responsibilities than yet exists, but despite this the story of medicine is one of progress. The public sympathy with medicine increases, and it will continue to do so in proportion to the advancement of education and of that wide spread of sound medical doctrine to which we are proud to be able in some measure to contribute.

◆

Heroes of Thought.

"Hellenists, professors of Roman law, and enthusiasts of Romantic or Christian medievalism are *not to be easily* convinced that an intelligible stream of progress can be shown in the long, broken, stormy course of evolution from Solon and Thales to the nineteenth century of Cavour and Darwin. But a true philosophy of history can trace a real and consistent sequence." Thus writes Mr. Frederic Harrison in an introduction to a volume of "Essays and Addresses" by the late John Henry Bridges.[1] The first half of this book is devoted to essays in Positivist doctrine, of which, as is well known, Dr. Bridges was one of the most distinguished exponents in this country. One of these essays, entitled "The Philosophy of History," might well serve as a text for the whole book, for in it an attempt is made to sustain one of the central tenets of the Positivist school—that of the principle of historical growth or of continuity in progress.

In tracing the course of Western civilisation during the 25 centuries since its dawn in the times of the great Greek thinkers, it is claimed that the state of the speculative faculties of mankind is the prime agent in social advance and progress, and further that the social change of each successive period resulted not from the practical life of that period but from the previous state of belief and thought, and that therefore the order of human progression *depends mainly, or at any rate largely, upon the order of* progression in the intellectual convictions of mankind. When we remember the importance assigned by Comte to mathematics as the basis of systematic thought, it is not surprising to find that Dr. Bridges maintained that the most original achievement of Greece was neither her poetry nor her metaphysical philosophy but her separation of mathematics, the humblest and yet the most fundamental of the abstract sciences, from the confused collection or inchoate mass of empirical knowledge which mankind had previously accumulated. Dr. Bridges complained that history as commonly taught does not include the history of science and that even now the sociological importance of its great discoveries is only just beginning to be recognised. In illustration of the law of continuity he shows how the discoveries in geometry and mathematical astronomy made by the Greeks were adopted and extended by the Arab schools of Bagdad and Cordova, to be continued by the Western thinkers of the thirteenth century, men such as Grosseteste and Roger Bacon. In his opinion there was no dark age, even in the apparent retrogression of mediæval Europe before the Renaissance, for he maintained that whereas in ancient Greece there was a great development of the intellectual aspects of human faculties and in ancient Rome great practical activity in political and warlike spheres, the third or spiritual part of man's threefold nature was but little advanced till these so-called dark ages. In these times learning began to extend from the favoured few to the many through the medium of the monastic teachers, while the great social revolution from servile to free labour began. Dr. Bridges illustrated his views in some commemorative addresses which form the second part of this book. These lectures were delivered on certain days in the "*Positivist Calendar of Great Men.*" Among these, he treats of Thales, Roger Bacon, and Harvey as heroes of thought; Dante, Calderon, Corneille, and Diderot as heroes of literature.

The account given of the importance to mankind of the elementary mathematical abstractions of THALES and the other Greek geometers is exceedingly interesting. Starting from the practical problems involved in land measurement they laid the foundations of physics and astronomy and evolved certain fundamental laws—indeed, the first laws of nature to be grasped by man. It is hard for us now to conceive without careful thought of the great advance made in the two apparently simple abstractions of the line and the angle, and yet they form the basis of all measurement and without them no calculation or accurate mensuration would be possible. The further conception of the triangle, the simplest possible figure, was the one in connexion with which THALES made his greatest discoveries, among which the law that the three angles of any triangle were equal together to two right angles is one of the most familiar. Another great law discovered by this master mind was that of the similarity of two figures of unequal sides and equal angles by means of which he taught the Egyptians how to measure the height of their pyramids. This was done by measuring the length of the shadow cast when the sun was halfway between the zenith and the horizon, since at that moment the shadow of a stick placed upright in the ground was found to be equal to the length of the stick itself. Without these great fundamental conceptions and the laws deduced therefrom there could have been no astronomy, no mechanics, no navigation, and no true conception of order which is in turn the basis to which science endeavours to reduce the complex problems met with in biological and sociological studies.

---

[1] Essays and Addresses, by the late John Henry Bridges, M.B., F.R.C.P., sometime Fellow of Oriel College, Oxford; late Medical Metropolitan Inspector to the *Local Government Board.* With an Introduction by Frederic Harrison. London: Chapman and Hall, Limited. 1907. *Pp. 307. Price 12s. 6d.* net.

It is a long step from THALES to ROGER BACON, from the ancient to the mediæval, but BACON stands out from the schoolmen as a great philosopher and a practical man of science, and *Dr. BRIDGES's* long study and special knowledge of the great Franciscan friar are here summarised in a most illuminating essay. The influence upon his career of his early association with GROSSETESTE at Oxford, who probably directed his attention towards science, the importance of his introduction to the Arabian adaptations of Greek discoveries through the agency of MICHAEL SCOTT, and the effect of his whole-hearted attachment to the Franciscan order are all clearly indicated. It is only in recent times that we have realised what we owe to Arabian philosophers and men of science who preserved what the Greeks had discovered in arithmetic, geometry, astronomy, natural history, and human anatomy. Moreover, the Arabian and Moorish schools in many instances made great advances, since their instruments of observation were more accurate than those of the Greeks. They laid the foundations of algebra and of optics. They adopted, if they did not discover, the decimal system, and they promoted the study of trigonometry, while their advances in chemistry and in medical sciences were truly remarkable. ROGER BACON was one of the first to render this great store of Eastern knowledge accessible to Western thinkers, his object being to show the West superior to the East and to advance learning through religious agencies with a view to the reform of education and the promotion of knowledge. His "Opus Majus" is one of the most remarkable surveys of knowledge extant and shows him to be greatly in advance of his contemporaries; indeed, he has been described as a man born some three centuries before his time. He devotes the earlier sections of his work to the four great obstacles to wisdom—namely, undue deference to authority, custom, popular prejudice, and unwillingness to confess ignorance. His instruments for advancing the studies of Western Europe were philology, mathematics, and experimental research, and to these the second, third, fourth, and fifth sections of the "Opus Majus" were devoted. To mathematics he attached the greatest possible importance, describing it as the key and entrance-gate of science. His application of mathematics to geography led him to a careful study of geography and to the compilation of a treatise thereon. He pointed out the necessity for a reform of the Julian Calendar which was delayed for three centuries after his death before it was carried out. The seventh section of the "Opus Majus," of which only part is preserved, dealt with practical reason and ethics and is the crowning of his work. This essay of Dr. BRIDGES is the most interesting short study that we have read on this great philosopher, and as Mr. HARRISON writes in his introduction, makes one wonder "if we are right in putting FRANCIS BACON on a pedestal higher than that occupied by ROGER."

The third of these commemorative addresses, entitled "Harvey and his Successors," was delivered as the Harveian Oration before the Royal College of Physicians of London, in 1892. Here again the importance of mathematics in relation to science is emphasised. HARVEY was born at the time when England gave birth to her greatest men in literature, philosophy, and science, to quote Dr. BRIDGES, "the greatest period of English history." At Padua he studied under FABRICIUS and may well have come under the influence of GALILEO, who was then attracting students from all parts to Padua, and although there is no record of personal acquaintance between the two men there can be little doubt that the influence of GALILEO's physical advances was felt by HARVEY, who, as Dr. BRIDGES wrote, "came back from Padua with the sense that Nature was not merely to be observed but measured." HARVEY's great work was the application of scientific methods to the study of living organisms, and by this means the complex alchemistic or humoral explanations of vital processes were at once disproved. Dr. BRIDGES traced in this address the influence of HARVEY's work upon his contemporaries and successors. The appreciation of his work by DESCARTES and the combined influence of his discoveries and the Cartesian philosophy in leading to the foundation of scientific medicine are discussed. The origin of the iatro-mathematical or iatro-physical and the chemiatric schools is traced and the subsequent foundation of an animist school by STAHL at the end of the seventeenth century is outlined. It was not, however, until the eighteenth century that biology became recognised as a distinct science with special methods, but the great discoveries of HARVEY were the direct outcome of the mathematical and physical discoveries made in his time. It has been said that science is measurement and Dr. BRIDGES's interesting addresses afford a striking illustration in support of the trite generalisation. The three great men whom he has studied were all heroes of thought who in face of obstacles applied accurate methods to the practical study of the problems which they investigated. It is highly instructive to follow the work of three such striking philosophers as the Greek geometer, the mediæval physicist, and the first scientific biologist. We can cordially commend this interesting collection of thoughtful essays to our readers as a stimulating and suggestive study.

The Coördination of Medical Studies.

To consider the beginnings of medical study at the beginning of the year seems to us appropriate, and we therefore publish in this issue two interesting contributions on the study of anatomy and embryology contributed by well-known teachers in different schools, feeling sure that they will afford abundant food for thought to the man who is at all concerned about the future of medical education in this country. Dr. ARTHUR KEITH in his address to the students of the London Hospital very clearly sets forth a convincing case against the fashion of entirely divorcing the study of anatomy from that of physiology with the result that the average student starts on his professional career with his knowledge of the structure and the function of the human body stored away in two watertight compartments in his mind. It is a useful corrective to over-sanguine ideas as to the complete efficiency of the present state of medical education to be told by Dr. KEITH how recently we have fallen away from higher standards in our systematic teaching of anatomy. "Up to the end of the eighteenth century," he says, "there was a strong school of British anatomists who regarded dissecting as a means for obtaining not a description but an understanding of the human body;" and surely this was the ideal of the great anatomists of all past ages as witness HEROPHILUS and GALEN amongst the ancients, EUSTACHIUS, FALLOPIUS, STENO, and SYLVIUS in succeeding centuries after the mediæval revival of the neglected science, and, greatest of all, WILLIAM HARVEY and the two HUNTERS at whose handiwork of dissection we may still look with our own eyes. What would JOHN HUNTER have thought, what would he have said, could he have looked forward to see his methods of thinking and teaching entirely superseded by the brilliant categorical and purely descriptive anatomy which the schools of Paris even in HUNTER'S lifetime were setting up?

The British student sought Paris a hundred years ago because the difficulty of obtaining subjects for dissection hampered his teachers at home and not because he had any fault to find with their teaching. But Dr. KEITH is right in pointing out that the method of anatomical instruction thus started soon became established in England as a custom, and even the old concession made by authors to the cause of the solidarity of medicine in writing on "Anatomy, Descriptive and Surgical," is lacking in many more modern treatises, excellent indeed after their sort, but composed of descriptive anatomy pure and simple. There is no doubt that this divorce of structure from function is an error. Save for the very rare student with an inherent genius for one or other of these studies the sole aim of teaching a medical student anatomy and physiology is that he may become a scientific physician or a rational surgeon who has built his professional house on the solid rock of well-ascertained fact. What is required by medical students is instruction in theory and detail alike of the kind which will make the pathological processes which they are afterwards to study comprehensible to them. Teachers are wanted who can clothe the dry bones of their lectures on anatomy with the living tissues of physiology and morphology and render them yet more vital to the medical student by pressing into service illustrations from medicine and surgery, so that the warp of structure and the woof of function may be woven into a stout garment of knowledge to clothe the student's mind in the place of the patchwork cloak in which it must now too often go forth, shivering on a stormy journey. Instances arise of the need of teaching of this sort in the consideration of every system in the body, for the circulation, the respiration, the digestion, and the functions of the brain can be much better grasped by the simultaneous teaching of their anatomy and physiology. The physiological teacher is occasionally obliged to sketch the rough outline of the coarse anatomy of the subjects with which he deals, for often, as in dealing with the brain, he must do so to make himself understood at all, and he also either *in propriâ personâ* or through an assistant in histology devotes much care to teaching the microscopical structure of the various tissues; but it is to a much fuller extent that we would have the physiologist invoke his anatomy; might not he, for instance, occasionally direct more attention to the ordinary functions of muscles illustrated from gross anatomy instead of spending nearly all the time that he can give to them in the demonstration of their chemical and electrical niceties? Still more often does the anatomical teacher appear to us to miss the true reasons of the lessons which he is giving by avoiding the very mention of anything that savours of physiology, referring such subjects to the other department of the medical school. We would even suggest that examiners might rest content with a little less minute knowledge of ultimate divisions of small nerves and arteries and markings on bones when the time saved might be employed by students in gaining a good working idea of the human machine. How many men on first entering on clinical work can look at a patient and form a clear mental picture of his organs as they lie inside him and at the same time even faintly realise the ceaseless and multiple activities of their vital functions? The average student sitting for an examination in surgery knows the anatomy of hernia thoroughly, for he was brought up on it, but there are many more anatomical points the vital surgical importance of which might with equal advantage be impressed on the student of anatomy when he first learns it; whilst the physiological teacher could take many more illustrations than is his wont from the field of medicine. And in neither case need the student be taken into the wards; the pathological deviation from the normal could be explained by consideration of the normal.

Professor PETER THOMPSON'S lecture on the Study of Embryology bears testimony to the truth of the contention that medical studies are not well coördinated despite the ceaseless care that has been exercised in arranging the numerous systems. Embryology is a study the importance of which has been appreciated since the days of WILLIAM HARVEY at least; a great deal is now known about it which might profitably be the common knowledge of every medical student, and yet how often does it fall between the two stools of anatomy and physiology, each granting it but half-hearted support and relegating it to one or two scrambled lectures which are neither complete in themselves nor complementary to each other. The teaching of the development of the fœtus in utero is indeed often largely handed on to a lecturer in midwifery who has only just enough hours at his disposal to summarise the bare facts of obstetrics and might reasonably suppose his hearers to come equipped with the physiology of fœtal development and even of the normal processes of birth so far as they fall under the headings of anatomical and physiological functions. The present medical curriculum is allowed on all hands to require lightening. The average student has to learn a large quantity of things that will be of no use to him and has to spend an extravagant amount of time in acquiring the knowledge. One method at least of economising time and labour would be to teach anatomy and physiology for the compulsory courses far more directly in relation to the professional career.

Annotations.

"Ne quid nimis."

SUGAR.

SUGAR is often given a bad name from a physiological standpoint but in many instances it is questionable whether it is deserved. It seems inconceivable that the bountifulness with which the world is supplied with sugar should mean anything else than that it is designed for human food. Sugar is one of the most powerful foods which we possess as it is the cheapest, or, at any rate, one of the cheapest. In muscular labour no food appears to be able to give the same powers of endurance as sugar; and comparative practical experiments have shown without the least doubt that the hard physical worker, the athlete, or the soldier on the march is much more equal to the physical strain placed upon him when he has had included in his diet a liberal allowance of sugar than when sugar is denied to him. Trophies, prizes, and cups have undoubtedly been won on a diet in which sugar was intentionally a notable constituent. It has even been said that sugar may decide a battle and that jam after all is something more than a mere sweetmeat to the soldier. The fact that sugar is a powerful "muscle food" accounts probably for the disfavour into which it falls, for a comparatively small quantity amounts to an excess, and excess is always inimical to the easy working of the digestive processes. A strong solution of sugar is irritating to the tissues, will set up superficial inflammation, and may produce a form of eczema. It is well known that an excessive diet of sugar irritates the mucous membrane of the stomach and encourages the production of mucus and of a highly acid gastric juice. The ingestion of much sugar spoils the appetite. Children who have been tempted to over-indulge in "lollipops" between regular eating times do not want their ordinary meal. The schoolboy spoils his dinner by eating too many sweet things before that meal. An over-indulgence in sweet liqueurs, in sweet ices, and in "crystallised" fruits after dinner retards the digestion of the meal. Sugar satiates; it is a concentrated food. Where sugar does harm, therefore, it is invariably due to excess. Taken in small quantities and distributed over the daily food intakes sugar contributes most usefully in health to the supply of energy required by the body. In certain diseases, of course, the presence of sugar in the diet is plainly undesirable. Generally speaking, however, there is a prejudice against sugar which is not justified by physiological reasoning—at all events, when it is eaten in moderation; and it is a curious fact that the man who practically abstains from sugar, or reduces his diet to one almost free from carbohydrates in favour of protein foods such as meat, often shows feeble muscular energy and an indifferent capacity for physical endurance.

PRIVATE PRACTICE BY GOVERNMENT SERVANTS IN INDIA.

THE question of remuneration for private work performed by Indian medical officers in their spare time has again risen to the surface, the motive power that caused the resurrection being, as usual, jealousy. In a long and bitter letter to the *Pioneer*, signed "Pro Bono Publico," the writer either begs the question or else relies upon assertion. "I know of many cases," he says, but instances none, "in which Indian chiefs have appealed to their political agents against the fees which the agency surgeons were charging, and *everyone with any knowledge of the subject* must be aware how the present legislation restricting fees has been brought about chiefly through the enormous fees which certain members of the I.M.S. charged to Indian chiefs." The italics are ours. When an anonymous writer makes unsupported statements they have no importance. We need not accordingly occupy more space with this portion of the attack. Proceeding with his diatribe, "Pro Bono Publico" asserts that "the ordinary Indian doctor has no more knowledge, except of special tropical diseases, than the usual English country practitioner who charges 7*s*. 6*d*. or 10*s*. per visit, and in respect of his knowledge of women's diseases he is generally partly inferior, yet he demands the fees of a first-class London specialist (who only charges a guinea per visit after the first visit) in addition to drawing his Government salary. Safe in the knowledge that he has his Government pay and that he is entirely free from competition, the Indian civil surgeon has no incentive to keep up his professional knowledge, and the medical fossils which could be dug out of many of the smaller stations in India would fairly startle their brethren at home." The only use served by vituperation of this calibre consists in the exposure of the writer's animus. That the members of the Indian Medical Service are second to none either in professional knowledge or in general intelligence is shown by the marks and places which they obtain in competitive examinations. There is not a session of the London School of Tropical Medicine where the class fails to include several Indian medical officers, ranking from colonel to lieutenant, the time thus devoted being deducted from private leave. The animus alluded to above assumes a very unpleasant form in the remarks which "Pro Bono Publico" sees fit to make regarding the losses recently sustained by the Indian Medical Service through devotion to duty. "How many men in all other branches of the Indian services die at their posts," he exclaims, "and lose their lives in the execution of their duty! Why should such deaths constitute a special claim in the case of the I.M.S. and not in the case of the other services?" To what is "Pro Bono Publico" referring? He further asserts that the *right* to accept private practice which is enjoyed by officers of the Indian Medical Service is due to long-established custom, and graciously adds that it may be admitted as "a concession which is granted to *no* other profession." It may have surprised him to learn that the right in question was granted by Act of Parliament which has never been repealed (13 George III., c. 63). In its editorial columns the *Pioneer* fully exposes the inexactitudes with which the letter of its correspondent abounds. "In the case of the law," says the *Pioneer*, "which approximates cordially commend this interesting collection of thoughtful essays to our readers as a stimulating and suggestive study.

The Coördination of Medical Studies.

To consider the beginnings of medical study at the beginning of the year seems to us appropriate, and we therefore publish in this issue two interesting contributions on the study of anatomy and embryology contributed by well-known teachers in different schools, feeling sure that they will afford abundant food for thought to the man who is at all concerned about the future of medical education in this country. Dr. ARTHUR KEITH in his address to the students of the London Hospital very clearly *sets forth a* convincing case against the fashion of entirely divorcing the study of anatomy from that of physiology with the result that the average student starts on his professional career with his knowledge of the structure and the function of the human body stored away in two watertight compartments in his mind. It is a useful corrective to over-sanguine ideas as to the complete efficiency of the present state of medical education to be told by Dr. KEITH how recently we have fallen away from higher standards in our systematic teaching of anatomy. "Up to the end of the eighteenth century," he says, "there was a strong school of British anatomists who regarded dissecting as a means for obtaining not a description but an understanding of the human body;" and surely this was the ideal of the great anatomists of all past ages as witness HEROPHILUS and GALEN amongst the ancients, EUSTACHIUS, FALLOPIUS, STENO, and SYLVIUS in succeeding centuries after the mediæval revival of the neglected science, and, greatest of all, WILLIAM HARVEY and the two HUNTERS at whose handiwork of dissection we may still look with our own eyes. What would JOHN HUNTER have thought, what would he have said, could he have looked forward to see his methods of thinking and teaching entirely superseded by the brilliant categorical and purely descriptive anatomy which the schools of Paris even in HUNTER'S lifetime were setting up?

The British student sought Paris a hundred years ago because the difficulty of obtaining subjects for dissection hampered his teachers at home and not because he had any fault to find with their teaching. But Dr. KEITH is right in pointing out that the method of anatomical instruction thus started soon became established in England as a custom, and even the old concession made by authors to the cause of the solidarity of medicine in writing on "Anatomy, Descriptive and Surgical," is lacking in many more modern treatises, excellent indeed after their sort, but composed of descriptive anatomy pure and simple. *There is no doubt* that this divorce of structure from function is an error. Save for the very rare student with an inherent genius for one or other of these studies the sole aim of teaching a medical student anatomy and physiology is that he may become a scientific physician or a rational surgeon who has built his professional house on the solid rock of well-ascertained fact. What is required by medical students is instruction in theory and detail alike of the kind which will make the pathological processes which they are afterwards to study comprehensible to them. *Teachers are wanted* who can clothe the dry bones of their lectures on anatomy with the living tissues of physiology and morphology and render them yet more vital to the medical student by pressing into service illustrations from medicine and surgery, so that the warp of structure and the woof of function may be woven into a stout garment of knowledge to clothe the student's mind in the place of the patchwork cloak in which it must now too often go forth, shivering on a stormy journey. *Instances* arise of the need of teaching of this sort in the consideration of every system in the body, for the circulation, the respiration, the digestion, and the functions of the brain can be much better grasped by the simultaneous teaching of their anatomy and physiology. The physiological teacher is occasionally obliged to sketch the rough outline of the coarse anatomy of the subjects with which he deals, for often, as in dealing with the brain, he must do so to make himself understood at all, and he also either *in propriâ personâ* or through an assistant in histology devotes much care to teaching the microscopical structure of the various tissues; but it is to a much fuller extent that we would have the physiologist invoke his anatomy; might not he, for instance, occasionally direct more attention to the ordinary functions of muscles illustrated from gross anatomy instead of spending nearly all the time that he can give to them in the demonstration of their chemical and electrical niceties? Still more often does the anatomical teacher appear to us to miss the true reasons of the lessons which he is giving by avoiding the very mention of anything that savours of physiology, referring such subjects to the other department of the medical school. We would even suggest that examiners might rest content with a little less minute knowledge of ultimate divisions of small nerves and arteries and markings on bones when the time saved might be employed by students in gaining a good working idea of the human machine. How many men on first entering on clinical work can look at a patient and form a clear mental picture of his *organs* as they lie inside him and at the same time even faintly realise the ceaseless and multiple activities of their vital functions? The average student sitting for an examination in surgery knows the anatomy of hernia thoroughly, for he was brought up on it, but there are many more anatomical points the vital surgical importance of which might with equal advantage be impressed on the student of anatomy when he first learns it; whilst the physiological teacher could take many more illustrations than is his wont from the field of medicine. And in neither case need the student be taken into the wards; the pathological deviation from the normal could be explained by consideration of the normal.

Professor PETER THOMPSON'S lecture on the Study of Embryology bears testimony to the truth of the contention that medical studies are not well coördinated despite the ceaseless care that has been exercised in arranging the *numerous systems.* Embryology is a study the importance of which has been appreciated since the days of WILLIAM HARVEY at least; a great deal is now known about it which might profitably be the common knowledge of every medical student, and yet how *often does it* sampling it is found that the permitted limits of moisture have been exceeded. It may be gathered from the circular that routine inspection of the registered factories will be made by officers of the Board of Agriculture. The circular points out, however, that under Section 2 of the new Act local authorities have powers to authorise any officer who is authorised to procure samples under the Sale of Food and Drugs Acts to enter any registered butter factory for the purpose of inspection of processes and taking samples. These powers may be found useful by medical officers of health in cases where there is reason to question the wholesomeness of the methods of manufacture carried on in the premises registered with their authorities; and it would probably be advantageous to all medical officers of health in the districts covered to arrange to be supplied with information as to the registered premises and with the necessary authorisation to inspect any of them.

PNEUMOCOCCIC INFECTION OF SEROUS MEMBRANES.

IN the *British Journal of Children's Diseases* for November, 1907, Mr. H. S. Clogg has reported the following case of pneumococcic infection of serous membranes which presents several points of interest. A girl, aged four and a half years, was admitted into hospital on Sept. 2nd, 1907. She became ill on July 28th with double pneumonia. The crisis occurred on the fifth day but though the temperature remained normal, or nearly so, improvement was not satisfactory. The dulness at the bases of the lungs persisted and moist sounds were heard all over the chest, except at the right apex where the breathing was markedly blowing. Towards the end of the second week the abdomen was somewhat swollen. The child lost flesh, the pulmonary signs did not clear up, the breathing became gradually more embarrassed, and the abdomen continued to swell, but the temperature remained practically normal. On admission she was thin and pale, there were considerable dyspnœa and cyanosis of the lips, the temperature was 100·2° F., and the pulse was 140. The apex beat of the heart could be neither seen nor felt. The heart sounds were best heard over the left edge of the sternum, about the level of the fourth costal cartilage. The breath sounds were distinct anteriorly as low as the third rib; below this they were faint and there was dulness to percussion. On the left side was marked dulness to percussion and the breath sounds were very faint. Posteriorly as high as the mid-scapular region there was dulness over both lungs, vocal fremitus was absent, and the breath sounds were faint. The abdomen was much distended with fluid. Both sides of the chest were explored. The result on the right side was negative; from the left chest pus was withdrawn. Two hours later under chloroform a needle was again inserted in the left seventh intercostal space and a few drops of pus were withdrawn; a rib was resected and the parietal pleura was incised. The latter was much thickened. The surface of the lung beneath showed a small area of lymph. By inserting a finger into the pleural cavity and gently sweeping it in all directions pus was found. Evidently when the chest was explored a small abscess had been entered and evacuated. The exposed lung appeared to be pneumonic. A small gauze drain was inserted and the greater part of the wound was sewn up. The child stood the operation badly; she became collapsed, the cyanosis increased, and the pulse was hardly perceptible. Under the belief that the dyspnœa was partly due to the pressure of the abdominal fluid on the lungs, paracentesis abdominis was performed about 24 hours after the operation and 13 ounces of pus were withdrawn. The respiration improved and a few hours later the abdomen was opened in the middle line below the umbilicus and three or four pints of very thick, yellowish-green pus were removed. Further incisions were made in each loin and drainage-tubes were inserted in each wound. Drainage of the abdomen was satisfactory but the cyanosis persisted and the dyspnœa was undiminished. The temperature did not range above 99·6°. Two days later death occurred suddenly. At the necropsy the brain and meninges were found to be normal. The pericardium was distended with 16 ounces of thick greenish pus. Both the parietal and visceral layers were thickened and covered with thick layers of lymph. There was generalised double pleurisy with numerous recent adhesions. In the left pleural cavity at the level of the ninth rib were about two drachms of pus inclosed by recent adhesions. On the right side, about the level of the seventh rib, in the posterior scapular line was a similar collection. The upper lobe of the right lung showed some œdema, the middle and lower lobes considerable œdema. The upper lobe of the left lung showed some œdema; the lower lobe was very congested. The intestines were covered by a layer of lymph and bound together by recent adhesions which here and there formed pockets inclosing pus. The intestines showed inflammatory changes. The pelvic peritoneum was severely affected but the pelvic organs were normal. Cultures from the pleuræ, pericardium, and peritoneum showed the pneumococcus in pure culture. The case seemed to have been an example of primary pneumonia with secondary infection of the pleuræ, pericardium, and peritoneum. There was no evidence that the abdomen had been infected by extension from the pleura or from the alimentary canal. The pericarditis was entirely overlooked. On admission the dyspnœa was thought to be due to an empyema, as pus had been found in the chest, but when exploration showed only a few drops of pus the dyspnœa was thought to be due to the pulmonary disease and possibly to be increased by the pressure of the abdominal fluid.

DELIRIUM TREMENS AND THE SUDDEN DEPRIVATION OF ALCOHOLIC DRINK.

IN the medical section of the recently published volume of Prison Statistics (1906) for England and Wales some pertinent comments are made as to the alleged onset of an attack of delirium tremens as the result of a heavy drinker being suddenly and completely deprived of alcoholic drink. 212,000 persons were incarcerated during last year in local prisons and of these 132 died; three of this number had "delirium tremens" certified as a cause of, or as a condition at, death. 63,000 persons, exactly one-third of whom were females, were sent to prison for drunkenness; very many more prisoners were of course notorious drinkers, although they had committed other definite offences. 246 cases of delirium tremens were recorded, exactly one-quarter of this number being females; of these, four men and one woman were certified as insane and sent to asylums, 159 men and 59 women had recovered at the expiration of their sentences, and 16 men and six women were discharged at the end of their term. Another interesting fact is that epileptiform convulsions are stated rarely to be seen among alcoholic prisoners. There appears therefore to be little support for the old theory and practice of giving a man verging on delirium tremens "a hair of the dog that bit him."

THE PHYSIOLOGICAL ACTION OF COLLINSONIA CANADENSIS.

IN the *Répertoire de Pharmacie* M. Abal has dealt with the physiological action of *collinsonia Canadensis*. This plant contains a glucoside of the saponin type and a resin. The alcoholic extract of the root when given to animals in small doses produces hyper-excitability. In large doses this is followed by depression, leading to paralysis of central origin, with circulatory disturbances and irritation of the glandular most nearly to medicine, the principle of private practice is fully admitted. If the State had to maintain a *corps* of whole-time Government advocates and public prosecutors all over the country it would either have to pay a prohibitive sum or put up with very indifferent agents." Precisely so: the two cases are accurately on all fours; and moreover no Government, save for income-tax purposes, would venture to order its legal servants to furnish the details of their private incomes. In the case of medical officers the Government does make this inquisitorial demand, and, strange to say, *Indian Engineering*, usually so enlightened, contends that it is justified in so doing. Engineers in India are not allowed to engage in private practice but that is no reason for denying a reasonable privilege to another body of men. Our contemporary says that when it comes to a civil surgeon getting a lakh or two for any service the Government is wise to interfere. Perhaps so, but do such cases occur in real life? We do not believe it. It is but another instance of question-begging. We can assure the writer of the article entitled "Professional Fees" in *Indian Engineering*, dated Nov. 13th, that the virtual extortion of fabulous sums from rajahs (or from anybody else for that matter) by the Indian Medical Service does not occur, and the moral odium cast on an honourable service by such loose accusations is bitterly resented.

THE FINANCIAL CRISIS IN RELATION TO SUICIDE.

There is little doubt that the present financial stress in America has been coincident with a large number of suicides and it is of more than passing interest to consider whether the one is a natural accompaniment of the other and whether self-destruction must be considered as a common corollary to severe monetary losses. It must be borne in mind that the successful man of business is commonly a highly neurotic subject—in truth, he frequently owes his very success to his keen sensibility and his deftness in foreseeing the trend of coming events. Now men are prone to forget, or maybe they are ignorant of the fact, that the type of nervous system which endows them with so many advantages is a highly unstable mechanism and renders them more liable to sudden fatigue or mental aberration than the less sensitive system of their more lethargic neighbour. Sudden stresses are more likely to lead to impulsive acts than are adverse circumstances of gradual onset. Periods of monetary stringency caused by trade depression have not uncommonly been noted as cycles during which the incidence of insanity has fallen. Times of difficulty undoubtedly weigh heavily on some individuals but given a few weeks the man soon gets used to his altered circumstances and hardships alone seldom produce mental disorder. But this is not so with sudden calamity. The millionaire of yesterday who is faced with ruin to-day has received a severe mental shock, and a profound emotional disturbance such as this paralyses judgment. Now uncontrolled emotion is a common precursor of rash acts. The once prosperous man who is suddenly confronted with bankruptcy is liable to lose the very attribute by which he attained his success; judgment is replaced by impulse and he not uncommonly plunges deeper and deeper into the morass and his affairs become increasingly involved; nights are spent in vain attempts to disentangle himself from the impending disaster and he has no proper time for meals or sleep; he soon becomes physically weakened and this accentuates his mental distraction, symptoms of fatigue appear, and the mind becomes confused and in consequence irrational acts may be performed. It must further be borne in mind that suicidal acts are more common in the earlier periods of a mental illness than during the later phases, and this fact alone accounts for an appreciable number of deaths of persons who succeed in destroying themselves before their disorder is recognised. So far we have only referred to the class of financier who is not necessarily a speculator but frequently a man whose business is sound and legitimate, notwithstanding the fact that he is dealing in large sums of money. But there is another type of person whom we may designate as a common gambler, for his vocation is speculating with money that he does not possess, and his success or ruin is more dependent upon the caprice of fortune. Now gambling appeals very forcibly to a certain degenerate class or ne'er-do-wells. The life of such a person is a lottery; he plays to win but if he loses he has already thought out the remedy and suicide to him will appear to be little more than a move in the game. We do not believe that there are many such men, but a certain number do exist and their self-destruction goes to swell the total number of tragic deaths which are inseparable from every great financial crisis. Suicide may be the termination of a life spent in gambling or it may follow the downfall of the man who, either from pride or lack of moral courage, is unable to face comparative poverty or to see his family, who were once surrounded with luxury, driven to earn their living. In this way a sudden financial collapse must be held responsible for the wave of suicide which so commonly follows in its train, but the majority of deaths by self-destruction are brought about by far more complicated stresses which undermine both the physical and the mental health of the individual, and the culminating act is only done when the mind of the distracted person becomes so confused that impulse replaces judgment and voluntary attention.

THE NEW BUTTER AND MARGARINE ACT.

By this Act, which came into force on Jan. 1st, a statutory maximum limit of 16 per cent. of water is imposed in the case of all butters, with the exception of "milk-blended butter," which is to be allowed to have as much as 24 per cent. so long as it is sold by a name which is approved by the Board of Agriculture and one which is not "suggestive of butter or anything connected with the dairy interest." The names under which margarine is sold are to be subject to the same restrictions. It is, perhaps, open to question whether the new statutory limits for moisture in butter and margarine will very much benefit the consumer; a large proportion of both articles has certainly contained considerably less than 16 per cent. in the past. The principal advantage of the Act, however, is the substitution of a system of control at the port of importation (through the Customs authorities and the Government laboratory) and in this country at the place of manufacture for the present methods which are based almost wholly on analysis of purchased samples. These methods have constantly broken down in cases where small quantities of foreign oils and fats have been "blended" or worked in with natural butter with considerable profit to the blender. Places where butter is blended "by way of trade" will now have to be registered and no foreign fats are to be kept on such premises. Wholesale "blending" of butter and margarine making are not to be carried out on the same premises, although exceptions may be made for existing factories. Another considerable advantage of the Act is that it empowers the Local Government Board to schedule and to regulate the use of preservatives in butter, milk-blended butter, and margarine, and it may be hoped that this will speedily be done. A circular has now been issued by the Board of Agriculture as to the action which local authorities are recommended to take under the new Act. Apparently the principal duty required of them is to see that butter-blending, milk-blending, and margarine-making premises are all duly registered and to report to the Board of Agriculture cases where in course of ordinary severe pain occurred in the lower abdomen which was not increased by pressure. Repeated doses of a third of a grain of morphine gave little relief. Magnesium sulphate produced large evacuations and on the next day there was some improvement and the pain was located around the navel. The urine contained neither albumin nor sugar but was of a peculiar light-green colour. Fresh urine gave no reaction for nickel. 400 cubic centimetres were evaporated and incinerated. The ash was treated with hot concentrated nitric acid. After the removal of iron the filtrate gave with oxalic acid a faint greenish-white sediment, with caustic soda a slight greenish sediment, and with ammonium sulphide a brown colour. Blood examination showed: hæmoglobin 70 per cent., normal erythrocytes, a striking number of platelets in aggregation, and normal lymphocytes. Under symptomatic treatment and purgation recovery took place in ten days. The symptoms thus consisted of cachexia and anæmia followed by severe colic. Possibly nickel dust accumulated in the intestines and irritated them, and some was converted into a salt and absorbed into the blood where it produced the anæmia and blood platelets. Possibly also some of the other metallic dusts evolved in the patient's work exercised an adverse influence. He stated that many of his fellow workers frequently complained of ailments which they attributed to inhalation of aluminium dust. In the case related above it is noteworthy that although the dust was presumably inhaled there were no pulmonary symptoms.

DRUID POETRY AND MEDICINE.

AN ancient folk-song, "The Twelve Apostles," still sung at Christmas and on festive occasions by English rustics, has been found on examination to be a variant of the rhythmic chant in which the Druids, or medicine-men of the ancient Britons, recorded their wisdom. "The Twelve Apostles" in its Hampshire form is sometimes cited by its first line—"What is your one O?"—a question that has with its answer puzzled whole generations of people curious in such matters. In foreign variants of the song, whether Armorican, Slavonic, Southern German, or even Hebrew, the answer to the opening question is generally a statement of the Unity of the Godhead, but the English song differs from all its continental parallels in that it retains traces of pre-Christian mysticism, quite meaningless at first sight but partially explainable on reference to a Celtic version quoted by Aurélien de Courson in his "Histoire des Peuples Bretons." "What is your one O?"—the English query—receives the answer, from which rhyme and reason seem alike to have departed, "When the one is left alone, No more he can be seen O." We turn to de Courson's version, which must not be confounded with the Armorican Church Latin with its "Unus est Deus," and we find a Druid instructor telling his disciple that the One is Death. "There is no division for the number One, the unique necessity, Death, father of sorrow, nothing before, nothing after." "Two" is explained as "two oxen harnessed to an egg-shell. They drag it and they die. Behold the marvel." Then come the "three beginnings and the three endings, for man as for the oak, three celestial realms of Merlin, golden fruits, bright flowers, little children that laugh." Under these poetic symbols the Druids of the pre-Christian period doubtless veiled their teachings, astrological, physical, or medical. Some light is thrown on the nature of their medical apothegms by the Hebrew version above mentioned, where Nine is the nine months of a woman's gestation (in the English song it is "the triple trine," a mystic reference possibly to the same period). What the Druid medicine actually amounted to it is hard to say, though the modern Welsh bards still profess to know something about it through a kind of Masonic tradition. The Druids' wives, the Alraunes, are said to have had the care of warriors wounded in battle and of women in child-bed. The Druids themselves were probably dealers in simples and astrologers of a rough-and-ready kind, like "the wise women" of our own primitive country-sides. Some Celtic herbalist remedies linger, as we know, in the Scottish and Irish Highlands and among the descendants of the Cymri on both sides of the Channel.

THE AUSTRALASIAN MEDICAL CONGRESS FOR 1908.

WE are asked to remind our readers that the eighth session of the Australasian Medical Congress will be held in Melbourne this year under the presidency of Professor H. B. Allen, the session commencing on Monday, Oct. 19th, and terminating on Saturday, Oct. 24th. The subscription is 1 guinea and will entitle every member to a copy of the Transactions of the Congress; this should be sent to the general secretary of the Congress. The railway departments of Australasia will issue concession tickets to members for the return journey at special rates, particulars of which will be supplied to intending members by the State secretaries. It is anticipated that reductions in fares, similar to those granted in previous years, will be made by the Interstate Steamship Companies. The council of the University of Melbourne has granted the use of the buildings and the Government of Victoria has undertaken the printing of the Transactions. Addresses will be given in plenary congress by the presidents of the sections of medicine, surgery, pathology and bacteriology, and public health, whilst special meetings of the congress will be devoted to the consideration of (a) the relations of the medical profession to hospitals; and (b) syphilis. Any medical man resident in Great Britain desirous of attending the Congress or of becoming a member should write to Dr. H. O. Maudsley, at 8, Collins-street, Melbourne, who is acting as general secretary.

"POTENTIZATION" AGAINST SMALL-POX.

A STATEMENT contained in the Bulletin of the Chicago School of Sanitary Instruction to the effect that attempts are made to introduce children into the public schools on the strength of their being furnished with certificates from medical practitioners stating that the children have been "potentized" reads almost like ancient history. It carries us back, indeed, to the days of Lady Mary Wortley Montagu who first introduced the system of small-pox inoculation into this country from Constantinople. Apparently, however, "potentization" is usually induced by administering "variolinum" internally, this substance being prepared by triturating "matter" from a ripe small-pox vesicle with sugar of milk. Sometimes, however, the "variolinum" is rubbed on the arm. It is stated that, unlike inoculation, "potentization" has no protective influence over small-pox and that children thus treated may be easily vaccinated. But although we are told that this "potentization" is not recognised by health authorities no mention is made as to whether or not this custom has led to the spread of small-pox or why, as with inoculation in this country, the operation is not forbidden by law. Perhaps later issues of the Chicago Bulletin will contain additional data relative to this "potentization" and as to its historical relationship to the practice adopted by the Chinese of inserting small-pox crusts into the nostrils of the patients in order apparently that they might contract the disease by inhalation. It is difficult to ascertain whether there were amongst the Chinese any conscientious objectors to this crusting process but in so far as inoculation or engrafting is concerned it would appear from the writings of Madame Sevigné in 1718 that in Adrianople "every year thousands undergo the operation, and the French Ambassador says pleasantly that they take the small-pox system. The glucoside in mild doses acts as a feeble cardiac tonic, and in larger doses the irritant effects preponderate, giving rise in cold-blooded animals to asystole alternating with an increase of systolic energy. In warm-blooded animals there is a rapid lowering of arterial pressure with increased force of the heart beat. Though the resin acts less energetically it augments the action of the heart. It excites the secretions of the gastro-intestinal tract and provokes marked diuresis, probably owing to its action on the circulation as well as on the renal epithelium. The diuretic action is accompanied by an increased output of all the urinary constituents. The drug is chiefly used as a diuretic.

DEATH OF SIR JAMES HECTOR.

New Zealand has through the demise of Sir James Hector, M.D. Edin., F.R.S., K.C.M.G., the director of the Geological Survey Department, lost one of the most brilliant all-round men of science she has ever had. For nearly half a century he was the most conspicuous man of science in New Zealand, while his persistent journeyings into every nook and corner of the land brought him more or less personally into contact with every inhabitant of the colony who had any stake in its welfare and any share in its public life and progress. His multifarious activities were pursued until between four and five years ago, at which date he resigned from the public service. At that time he proposed to make a tour with the view of exploring the scenes of his Canadian explorations of 50 years ago—for he was employed on the Palliser Expedition from 1857 to 1860—but the scheme was abandoned owing to the death of his son and the brief remnant of his life was spent in retirement. It is not likely that in the future any man will be able to take so commanding a place in the scientific life of his country as Sir James Hector did in New Zealand, and we cannot do better than quote an appreciation of his many-sided genius from the *Wellington Post* which has been forwarded to us by our special correspondent in the colony. The fact is well brought out in our contemporary's sympathetic words that the all-round man of science must now be dying out—Sir James Hector was one of the last. "Science was not specialised in the days of Sir James Hector's youth as at present and with a vast faculty of observation and assimilation, fine reasoning powers, and exceptional executive ability, his almost encyclopedic knowledge was always at the disposal of his adopted country. It may seem paradoxic, but in Sir James Hector's case a list of scientific subjects on which he was not a recognised authority would be difficult to compile, they were so few. At the Philosophical Society he usually left the discussion of subjects in the higher mathematics, modern chemistry, or optics to others—in practically every other sphere he was on even terms with the leading men, and in many supreme. His acquaintance with animal and vegetable comparative physiology, and biology generally, was marvellous. A bone, a wing, a shell—an exceptional structure in any natural specimen under discussion—would be the text for an extempore discourse scintillating with wit and wisdom, illuminating, fascinating as a fairy tale, and invariably supported by original observation. He was a thorough meteorologist. His geological attainments were world-famous. He knew the physical geography of New Zealand and its outlying islands, the contours of its ocean deeps, its seismic and thermal lines, 'almost as he knew his alphabet.' On the native products of the colony and their practical uses he was the leading authority, and he was the author, among many other works, of a standard treatise on the phormium industry." Sir James Hector, as might be anticipated from such a record, was also prominent in the public advancement of science in New Zealand; it was always his particular aim to bring home to the people that in scientific knowledge, properly organised, must lie social salvation. He was one of the founders of the Philosophical Institute, which has just issued its thirty-ninth annual volume, and he held a prominent position on its council up to about five years ago. The Colonial Museum was established and built under his care. He organised the New Zealand Exhibition of 1865, which was a great success even when compared with much later exhibitions having the same object. Naturally he was ready to work in any useful directions for the development of education, and he became prominent in the executive work of the New Zealand University from its start. Such is the brief record of a man of most varied attainments who served his adopted country so well in many ways. His position was always thoroughly recognised by his brethren in science. He was associated by friendship and correspondence with the leading scientific men of the age and honoured by learned societies all the world over. In private life his high character, his kindly nature, and his genial disposition endeared him to a large circle of friends and the gap that he has left will never be exactly filled. There is a movement on foot to establish a medal in co nexion with the university in commemoration of the gre work which Sir James Hector did as Chancellor.

ROYAL COLLEGE OF SURGEONS OF ENGLAND: PRESENTATION TO MR. C. R. HEWITT.

ON Dec. 23rd, 1907, an interesting presentation took place at the Royal College of Surgeons of England. Mr. C. R. Hewitt, who was recently appointed a librarian at the Royal Society of Medicine, being the recipient of a piece of plate suitably inscribed and a cheque for 55 guineas in recognition of his 22 years' service in the library of the College. The gifts were subscribed for by some 75 friends as a token of esteem and good wishes for success in his new appointment. Professor William Osler made the presentation on behalf of the subscribers and in the course of a few well-chosen words recalled the valuable help which he had received from Mr. Hewitt many years ago in the College library. Professor Osler further said how pleased he was to see Mrs. Hewitt present on the occasion, as the piece of plate—a tea-caddy—would certainly be more appreciated by her than by her husband, and he therefore felt that he ought to present that to her. Mr. Henry T. Butlin, besides thanking Mr. Hewitt personally for the help which he had received on many occasions in the library, also thanked him on behalf of the Council of the College for his valuable assistance and genial manner to the readers generally. Mr. Butlin said that the Council felt that they had lost an official whose place would be difficult to fill. Mr. Hewitt's new appointment would, however, give him wider scope in which to show his ability as a library bibliographer. Mr. Hewitt returned thanks for the kind words spoken by Professor Osler and Mr. Butlin and recorded his appreciation of the sound advice and kind assistance that he had received whilst in the service of the College from the librarian, Mr. Victor G. Plarr.

NICKEL POISONING.

IN the *Journal of the American Medical Association* of Nov. 9th, 1907, Dr. George Richter has recorded a case of a very rare condition—nickel poisoning. The patient was a man, aged 24 years, a polisher of aluminium, copper, and brass, but mostly of nickel. In the process considerable dust was evolved which was only partly removed by "sucking blowers." He consulted Dr. Richter on account of great prostration, a sense of pressure on the stomach, and slight headache, which he attributed to influenza. His skin was pale and his complexion was sallow. The tongue was slightly coated and on its left margin and the corresponding buccal surface was extensive leucoplakia. In the evening health. Hence nearly every woman's paper contains a column generally headed "Health and Beauty" or some similar title, in which correspondents ask idiotic questions and in many instances get equally idiotic answers. If Miss Rossie would add to her labours in the instruction of prisoners by instructing those outside prisons as well, avoiding, of course, medical questions, she would be deserving of the gratitude of many.

THE EXHUMATION OF THE BODY OF MR. T. C. DRUCE.

THE opening of the grave of the late Mr. T. C. Druce at Highgate has set at rest the doubt which apparently existed in some minds as to whether the coffin bearing his name and placed in his family vault in 1864 might contain nothing more than rolls of lead used for purposes of deception at a mock funeral. It is difficult to understand such doubts affecting anyone who heard or read the evidence given at the hearing in the Probate Division in December, 1901,[1] unless he believed that the grave might have been tampered with since the incidents then deposed to by the medical witnesses took place. It is not too much to say that if no human remains had been found in the coffin opened on Dec. 30th last the only alternative to a theory of interference subsequent to the funeral would have been the supposition that not only Mr. Herbert Druce but Dr. Edmund Shaw and his partner, Mr. W. Blasson, as well as the housekeeper, Catherine Ann Bayley, committed deliberate perjury in the suit tried before Mr. Justice Gorell Barnes. Their evidence was perfectly clear that a gentleman well known to them as Thomas Charles Druce, who had been ill for some time and who had been operated upon by Sir William Fergusson, died and was by them placed in his coffin, which they, or some of them, followed to the grave. At the same trial a statement, since frequently repeated, to the effect that there was an irregularity in the certificate of the cause of death in that it did not bear the signature of any medical man, was fully explained, the simple explanation being that in 1864 the law did not require death certificates to be signed. The effect of the recent exhumation has been to corroborate the evidence of two medical practitioners of unimpeachable integrity, independent witnesses whose testimony was in no way shaken when it was originally given, and which consequently required nothing to confirm it, but at the same time the popular interest in the matter and the unwillingness of the public to be undeceived rendered the opening of the coffin, with the resulting ocular demonstration that it contained a dead body, desirable. What this result may be upon the litigation which in various forms is still pending, and upon public opinion with regard to it, we do not, of course, discuss.

THE second annual dinner of the past and present students of the Royal London Ophthalmic Hospital will take place at the Trocadéro Restaurant, Shaftesbury-avenue, W., on Wednesday, Jan. 29th, at 7.45 for 8 p.m., with Sir John Tweedy, consulting surgeon to the hospital, in the chair. Each student is entitled to introduce two guests and tickets (price 10s. 6d. each, exclusive of wine) may be had on application to either of the honorary secretaries, Mr. Arnold Lawson, 12, Harley-street, London, W., and Mr. J. Herbert Parsons, 27, Wimpole-street, London, W.

THE opening lecture of the Mount Vernon Hospital post-graduate course will be given by Sir Thomas Clifford Allbutt, F.R.S., consulting physician to the hospital, in the lecture room at the central out-patient department, 7, Fitzroy-square, London, W., on Thursday, Jan. 9th, at 5 P.M. The subject of the lecture, to which medical practitioners are invited, will be Angina Pectoris.

A TELEGRAM from the Governor of the Mauritius received at the Colonial Office on Dec. 27th, 1907, states that for the week ending Dec. 26th there were one case of plague and one death from the disease.

Mr. C. A. Ballance has been elected an honorary fellow of the American Laryngological, Rhinological, and Otological Society.

Mr. Malcolm A. Morris, F.R.C.S. Edin., has been appointed a Knight Commander of the Royal Victorian Order.

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

On the Sanitary Circumstances and Administration of the Urban District of Whitby, by Dr. R. A. FARRAR.[1]—Whitby, already described in 1538 as "a great fischar towne," had become a prosperous seaport in the reign of Queen Elizabeth, when it did a good trade in the manufacture of alum. In 1753 the town entered on a new era, as ships began to sail from Whitby to the Greenland seas for whale fishing. Following on the whale fishing came a period of wooden ship-building which gave place to an iron ship-building industry which has only ceased within the last few years owing to the insufficiency of the harbour. The decay in ship-building was for a time more than compensated by the development of the jet trade. In the early days of Queen Victoria's reign, particularly after the death of the Prince Consort, jet ornaments had an extraordinary vogue and at one time as many as 1400 hands were employed in their manufacture. "Line" and herring fishing brought some prosperity to the town until a few years ago, but the silting of the harbour has rendered the passage of the harbour bar so unsafe that the port has practically been abandoned by all but a few local fishing cobles. At the present day Whitby's only source of prosperity is its annual influx of summer visitors and excursionists. All these vicissitudes have left their mark, as Dr. Farrar shows, on the housing conditions of the town. As the whale fishing and ship-building industries increased the good and substantial houses on the East Cliff were surrounded or superseded by an abundance of jerry-built houses and narrow courts. When the jet industry flourished jet factories and warehouses were crowded into every corner which could be made available. The "slums" of Whitby, about which there has lately been much local agitation, are in consequence of these conditions slums in a very real sense. Not only is the crowding on area excessive, and greatly aggravated by the presence of derelict jet factories, but the courts and dwellings themselves are in many cases beyond repair and though occupied are quite unfit for human habitation. The entries into the courts are seldom more than three feet wide and the passages dividing the blocks of houses have generally a like width. The lower rooms are in consequence almost invariably dark. Many of the houses are damp owing to the walls being built against the hillside. The bedrooms are often mere cupboards contrived in the living room, containing less than 200 cubic feet air space and kept closed in the daytime. Dr. Farrar has no doubt that the health of the inhabitants of these slum areas in Whitby suffers from the conditions of living which result from the character of these dwellings. In examining the school children he found that the physical condition of those on the east side of the town was markedly inferior to that of children on the west, and, in particular, children from one of the collections of "slum" courts could by their physical deterioration be as a rule picked out at a glance from the other scholars. The report points out that there by way of diversion as they take the waters in other countries. There is no example of anyone who has died in it, and you may believe I am well satisfied of the safety of this experiment since I intend to try it on my dear little son." As to the practice of inoculation in this country, there are probably persons still alive who underwent the operation, although none are likely to remember that the charge for the operation amongst medical practitioners was about half a guinea. But in those days there were no public vaccinators and hence no opportunities for boards of guardians to accord them the minimum fees.

THE MEDICAL DIRECTORY FOR 1908.

THE issue of this work for 1908 appeared with commendable promptitude in the third week of December, 1907. Comparing the edition for the current year with that for the year just past we see that the total number of names for 1908 is 39,703, as against 39,365 for last year, being an increase of 338. As regards the several regions into which the Directory is divided the number of names in the London list for 1908 is 6550, as against 6512 in 1907. The provincial list for England for 1908 contains 17,211 names, as against 17,080 in 1907; Wales for 1908 has 1256 names, as against 1232 for 1907; Scotland for 1908 has 3829 names, as against 3815 for 1907. The Irish list for 1908 contains 2660 names, as against 2672 for the past year. The list of practitioners resident abroad contains 4927 names, as against 4822 in 1907. The Naval, Military, and Indian Medical Services for 1908 number 3259 names, as against 3223 in 1907. It will thus be seen that there is a recorded increase in the numbers of the profession in every part of the kingdom except Ireland. The "Too Late" list for this year contains 11 names, two more than in 1907. The introductory chapter on the legal relations of medicine has become an acknowledged authority for reference, and as is universally known in the medical profession Messrs. J. and A. Churchill are the publishers of this indispensable work of reference.

THE DETECTION OF COCOANUT OIL IN BUTTER.

ONE of the most subtle forms of adulteration in the present day is the admixture of cocoanut oil with butter fat, the product being sold as genuine butter. Indeed, it has been asserted that almost pure cocoanut oil has been palmed off as pure butter. Hitherto the analyst has been baffled in his attempts at devising a method for the certain detection of cocoanut oil in butter, the sophistication being so cleverly accomplished that the mixture on examination is found to yield certain analytical factors which are consistent with those yielded by genuine butter itself. It is singularly opportune in view of the new measure for the control of the sale of butter which comes into force this year that a method has been projected which promises to place in the hands of the analyst a means of detecting this sophistication. In a note contributed to the *Chemical News* of Dec. 20th, 1907, Mr. T. R. Hodgson, B.A., A.I.C., of the analytical department of the University of Birmingham, shows that the oxygen equivalent of cocoanut oil is considerably less than that of pure butter fat. The oxygen equivalent is found by submitting the pure fats to the action of a standard solution of potassium permanganate for a time and afterwards determining the amount of permanganate left unreduced. One gramme of the filtered fat is weighed out into a flask and 25 cubic centimetres of a half normal alcoholic solution of caustic potash are added. The whole is heated under a reflux condenser for 30 minutes. After the saponification is complete the flask is detached from the condenser and the solution is evaporated to dryness. Distilled water is added to the residue and the whole is evaporated once more to dryness. The process is repeated until the whole of the alcohol has been dissipated. The residue is next dissolved in water and made up to 1000 cubic centimetres. 20 cubic centimetres are measured out and placed in a beaker and 50 cubic centimetres of a tenth normal solution of potassium permanganate are added and finally 50 cubic centimetres of a 50 per cent. solution of sulphuric acid. The beaker is then placed on the water bath (100° C.) for half an hour and the excess of permanganate is then determined by means of a standard solution of ferrous ammonium sulphate. The number of cubic centimetres of permanganate solution used multiplied by 4 gives the "oxygen equivalent," or the number of grammes of oxygen required to oxidise 100 grammes of the oil or fat. Pure butter fat gives an oxygen equivalent of 167·2. With 10 per cent. of cocoanut oil present the equivalent is 160·8, with 20 per cent. 152, with 30 per cent. 142·4, with 40 per cent. 136·0, with 50 per cent. 127·2, with 60 per cent. 118·4, with 70 per cent. 110·4, with 80 per cent. 103·2, with 90 per cent. 95·2, until pure cocoanut oil itself gives 87·2 as the "oxygen equivalent." It is to be hoped that this method will prove on continued trials to give trustworthy results and so to supply at last to the analyst a means of bringing to light a very subtle form of adulteration.

PROPOSED LOCAL GOVERNMENT BOARD INQUIRY INTO THE CAUSE OF SCARLET FEVER.

AT a meeting of the Metropolitan Asylums Board on Saturday, Dec. 7th, it was unanimously decided, on the motion of Dr. W. R. Smith,

> That in view of the continued prevalence of scarlet fever, notwithstanding the extensive isolation accommodation which has been provided, the Local Government Board be asked to cause an inquiry to be instituted into the cause of this disease; and whether any, and if so what, further means can be adopted for its prevention.

Dr. Smith submitted a table of figures which showed that in 1890 there were 15.330 cases of scarlet fever notified, or a ratio per 1000 of population of 3·7; in 1906 the cases notified numbered 20.329 or a ratio per 1000 of population of 4·3. In the acquisition of sites the Board had expended £234,104 and the cost of buildings and equipment amounted to £2,905,659. For that expenditure they had provided 8166 beds and they were in no way better off from the point of view of the spread of infectious disease by reason of that vast expenditure.

"CRUELTY TO CHILDREN" PRISONERS.

IN THE LANCET of August 20th, 1904, we commented favourably upon some lectures given by Miss Charlotte Smith Rossie to women prisoners in Portsmouth jail. The lectures were upon the subjects of hygiene and the care of children. An article by Miss Rossie appears in the current number of *The Sunday at Home*, in which she gives an account of some lectures which she delivered to sundry women prisoners who were undergoing punishment for cruelty to children. This offence, disgraceful as it is to have to say so, is by no means confined to the *injusta noverca*, who has throughout the ages gained an evil reputation, but in many cases mothers are as hideously cruel as it is possible to conceive. Miss Rossie claims to have influenced these prisoners for good and she makes one suggestion which seems to us worthy of notice by experts in prison sociology. It is that "cruelty" prisoners should not be put in a "star" class, for that means a privileged class, but that they should be placed in a separate class from the ordinary criminal, "as for the most part they are respectable married women" and an attempt should be made to teach them home duties. This, we think, is a good suggestion, for the average modern woman is singularly ignorant of home duties and of the commonest laws of mortality being recorded in Handley and in Bootle, where the rate was 1·6 per 1000. The 50 fatal cases of scarlet fever exceeded the numbers registered in any of the seven preceding weeks; the highest death-rate from this disease was 1·0 per 1000 in Burnley. The deaths from diarrhœa, which had been 89, 50, and 47 in the three preceding weeks, were 48 in the week under notice, and caused death-rates ranging upwards to 1·1 in Walsall and 1·4 in Merthyr Tydfil. "Fever" was not excessively fatal in any of the 76 towns. The number of scarlet fever cases under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had been 5676, 5591, and 5352 at the end of the three preceding weeks, had further decreased to 5035 on Saturday, Dec. 21st; 447 new cases were admitted during the week, against 623, 554, and 500 in the three preceding weeks. The deaths in London referred to pneumonia and other diseases of the respiratory organs, which had been 388, 355, and 348 in the three preceding weeks, were 347 in the week under notice, and were 94 below the corrected average number in the corresponding periods of the five years 1902–06. The causes of 36, or 0·7 per cent., of the deaths in the 76 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, and in 66 other towns; six uncertified deaths were registered in London, six in Sheffield, five in Birmingham, five in Liverpool, and two each in Preston, Gateshead, and Rhondda.

During the week ending Dec. 28th, 5860 births and 4527 deaths were registered in 76 of the largest English towns. The annual rate of mortality in these towns, which had been 16·0, 16·1, and 16·8 per 1000 in the three preceding weeks, declined again last week to 14·7 per 1000. During the 13 weeks of the quarter the death-rate averaged 15·5 per 1000, the rate in London during the same period being 14·9. The death-rates in the 76 towns last week ranged from 6·9 in King's Norton, 7·0 in Hastings, 7·4 in Southampton, and 7·6 in East Ham to 22·8 in Rhondda, 23·5 in Wigan, 23·6 in Ipswich, and 24·4 in South Shields. The 4527 deaths registered in the 76 towns last week were 633 fewer than the number in the previous week, and included 373 which were referred to the principal epidemic diseases, against 374 and 398 in the two previous weeks; of these 373 deaths 105 resulted from measles, 89 from whooping-cough, 71 from diphtheria, 44 from diarrhœa, 41 from scarlet fever, and 23 from "fever" (principally enteric), but not any from small-pox. No deaths from any of these epidemic diseases were registered last week in Hastings, Bournemouth, Reading, Handsworth (Staffs), Smethwick, Coventry, Wallasey, or West Hartlepool; among the other towns the death rates from these diseases ranged upwards to 3·6 in Rhondda, 3·9 in Burton-on-Trent, 4·8 in Tynemouth, and 9·3 in Ipswich. The fatal cases of measles, which had been 107 and 124 in the two preceding weeks, declined again to 105 last week, and caused death-rates ranging upwards to 1·3 in Salford, 1·6 in Bootle, 1·7 in Barrow-in-Furness and in Leeds, 2·7 in Swansea, 2·9 in Burton-on-Trent, 3·8 in Tynemouth, and 7·2 in Ipswich. The deaths from whooping-cough, which had been 107, 95, and 94 in the three preceding weeks, further fell to 89 in the week under notice, the highest death-rates from this disease being 1·1 in Northampton, 1·3 in Devonport, in Aston Manor, in Sunderland, and in Newcastle-on-Tyne, 1·4 in Ipswich, and 1·6 in Hanley and in Bootle. The fatal cases of diphtheria, which had been 57 and 62 in the two previous weeks, further rose last week to 71; this disease was proportionally most fatal in Norwich, where it caused a death-rate of 1·3 per 1000. The deaths from diarrhœa, which had been 47 and 48 in the two preceding weeks, declined again to 44 in the week under notice; the mortality from this disease was not excessive in any of the large towns. The fatal cases of scarlet fever, which had been 38, 40, and 50 in the three preceding weeks, fell to 41 last week, and caused death-rates ranging upwards to 1·1 in Walsall, 2·1 in Newport (Mon.), and 2·3 in West Bromwich. The 23 deaths referred to "fever" were three in excess of the number in the previous week, the highest death-rate from this cause being 1·1 in Northampton. There were 4999 scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital at the end of last week, against 5591, 5352, and 5035 at the end of the three preceding weeks; 353 new cases were admitted during the week, against 554, 500, and 447 in the three preceding weeks. The deaths in London referred to pneumonia and other diseases of the respiratory organs, which had been 355, 348, and 347 in the three preceding weeks, further declined to 317 in the week under notice and were 145 below the corrected average number in the corresponding periods of the five preceding years, 1902–06. The causes of 56, or 1·2 per cent., of the deaths registered in the 76 towns were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, West Ham, Bradford, Newcastle-on-Tyne, and in 42 other towns; seven uncertified deaths were registered in Liverpool, six in Birmingham, five in Warrington, three in Manchester, and two in each of nine other towns.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 19·3, 20·6, and 20·0 per 1000 in the three preceding weeks, increased to 20·8 per 1000 during the week ending Dec. 21st, 1907, and was 4·0 per 1000 above the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 13·7 in Aberdeen and 18·0 in Edinburgh to 27·4 in Leith and 30·5 in Dundee. The 724 deaths in these towns were 28 more than the number in the previous week, and included 126 which were referred to the principal epidemic diseases, against 111, 132, and 127 in the three preceding weeks; of these, 53 resulted from measles, 26 from whooing-cough, 14 from diarrhœa, 11 from diphtheria, seven from cerebro-spinal meningitis, three from scarlet fever, and two from enteric fever. These 126 deaths were equal to an annual rate of 3·3 per 1000, which was 2·0 per 1000 above the mean rate during the same period in the 76 large English towns. The fatal cases of measles, which had been 79 and 71 in the two previous weeks, further declined to 53 in the week under notice, and included 35 in Glasgow, 10 in Dundee, and five in Greenock. The deaths from whooping-cough, which had been 13 and 24 in the two preceding weeks, further rose to 26 of which 11 occurred in Glasgow, four in Edinburgh, four in Aberdeen, three in Perth, and two in Greenock. The fatal cases of diarrhœa, which had been 36, 21, and 18 in the three preceding weeks, further declined to 14 in the week under notice, and included eight in Glasgow and four in Edinburgh. The deaths from diphtheria, which had been nine and eight in the two previous weeks, increased again to 11, of which three occurred in Glasgow, three in Paisley, and two in Leith. Of the seven deaths from cerebro-spinal meningitis three were registered in Glasgow, two in Paisley, and one each in Edinburgh and Leith. The deaths referred to diseases of the respiratory organs, including pneumonia, which had been 167 and 161 in the two preceding weeks, further declined to 157 in the week under notice, but were 38 above the number in the corresponding week of last year. The causes of 25, or 3·5 per cent., of the deaths in the eight Scotch towns were not certified or not stated; in the 76 English towns the proportion of uncertified deaths registered during the same week did not exceed 0·7 per cent.

During the week ending Saturday last, Dec. 28th, the annual rate of mortality in the eight Scotch towns was 18·2 per 1000, against 20·6, 20·0, and 20·8 per 1000 in the three preceding weeks, and was 3·5 per 1000 above the mean rate last week in the 76 large English towns. Among the Scotch towns the death-rates ranged from 12·5 in Leith and 13·2 in Aberdeen to 24·2 in Greenock and 25·4 in Perth. The 632 deaths registered in these towns last week were 92 fewer than the number in the preceding week, and included 109 which were referred to the principal epidemic diseases, against 132, 127, and 126 in the three preceding weeks; of these 53 resulted from measles, 24 from whooping-cough, 14 from diarrhœa, seven from diphtheria, five from scarlet fever, three from enteric fever, and three from cerebro-spinal meningitis, but not any from small-pox. These 109 deaths were equal to an annual rate of 3·1 per 1000, which was 1·9 per 1000 above the mean rate last week from the principal epidemic diseases in the 76 large English towns. The fatal cases of measles, which had been 79, 71, and 53 in the three preceding weeks, were again 53 last week, and included 38 in Glasgow, eight in Dundee, four in Greenock, and two in Aberdeen. The deaths from whooping-cough, which had been 13, 24, and 26 in the three preceding weeks, declined again last week to 24, of which six occurred in Glasgow, six in Perth, three in Edinburgh, three in Dundee, three in Leith, and two in Greenock. The fatal cases of diarrhœa, which had been 21, 18, and 14 in the

the first proceeding necessary is to treat derelict tenement blocks, jet factories, and warehouses as obstructive buildings under the Housing of the Working Classes Act, with a view to letting in light and air to the remaining blocks. This could be done, Dr. Farrar notes, "without seriously impairing the effect of the huddle of red roofs which is one of the æsthetic charms of Old Whitby." The space thus gained could be utilised as open space in a variety of useful ways, and the authorities concerned should then use their powers to secure that the remaining blocks are put into habitable repair. Along with these measures it is desirable that a certain number of modern working-class dwellings should be erected. Action by the district council on these lines has been successfully taken at Alnwick and other old towns presenting similar problems. The district council, in the hope of rehabilitating the ship building and fishing industry of Whitby, is proposing to spend *no less than £95,000 on harbour* extensions and improvements and on the rebuilding of Whitby bridge. If the anticipation of increased prosperity is justified it will be essential to provide for increase in, and improvement of, the house accommodation which is available for the working-class population. If the anticipation is unlikely to be justified (and in view of recent extensions of competing ports the proposal seems open to some doubt) the Whitby council would probably be serving its town better by abandoning grandiose schemes and by spending a much more moderate sum on housing improvements which at least may be relied upon to yield a return in the form of the better health and physical conditions of the population.

On the Sanitary Circumstances and Administration of the Thingoe Rural District, by Dr. F. ST GEORGE MIVART.[2]—Many interesting matters are dealt with in this report which relates to a large rural district with some 14 000 inhabitants surrounding the borough of Bury St. Edmunds. Among these are the insanitary conditions of dairy farms, many of which supply London dairy companies, and the unsatisfactory conditions of housing which prevail. The want of more cottages is "bitterly felt" in this district, and this is little to be wondered at in view of the character of many of those which now exist. Dr. Mivart reports that often houses were in a ruinous condition, the holes in the plaster walls being plugged with old sacks and rags within or blocked with a piece of plank and odds and ends of timber without. Such houses were also leaky in other places—*e.g.*, round the door and window frames, and occupiers resort to all sorts of expedients to prevent the entrance of cold air in winter. Rain-water pipes when present are commonly broken and while allowing the water to stream down the house walls deliver it also upon the ground in proximity to foundations, the surface about the house being only in a few instances furnished with paving. As to cottage bedrooms the report points out that sometimes the first-floor space comprises two or three rooms, of which the back one has no direct supply of light and air at all. The following account of a cottage in Sicklesmere is given as an instance of the use to which first-floor space may be put without bringing about prosecution for overcrowding:—"Total first-floor space, about 13 × 15 × 7 feet = about 1365 cubic feet of space. A corner of this, sufficient to hold a bed, is screened off by a dwarf partition about 4 feet 6 inches high. The entire first-floor space is shared by six persons, viz., a widow, aged 40; two sons, aged 16 and 14; two daughters, aged 13 and 6; and, as a lodger, a brother-in law, aged about 50. No fireplace or back window. Ventilation only by front window 2 feet square and by the opening in the floor for the ladder staircase." In the living rooms the fireplaces are often so poor that "cooking of any useful kind would be almost impossible even if inmates had sufficient knowledge for this." Many cottage dwellings are going steadily to ruin There is special difficulty in getting repairs in "tied" cottages—i.e., those rented by the farmers for their labourers. It is sometimes said that stringency of building by-laws prevents building in rural areas, but in this district no by-laws as to new buildings are in force. It should be said, however, that the district council made an attempt some years ago to utilise the Housing of the Working Classes Act. Eight good semi-detached cottages in four blocks, with sufficient land, were erected at Ixworth in 1893 at a cost of £1700, obtained by loan repayable in 30 years. The innovation was subjected to much local criticism and ridicule under the name of the "Thingoe Folly." But Dr. Mivart found the houses all occupied; he gives the profit and loss account in connexion with them, and shows that when the loan is extinguished the council is likely to find itself well on the right side of the account. The experiment suggests that subject to some alterations, such as lengthening the borrowing period, it would be practicable to do much good by similar "follies" in other villages and hamlets. Too much stress must not be laid on the argument that properly built cottages of this kind must be let at a higher rent than the labourer can afford. Those who can afford the rent and go into these cottages in most cases vacate a better kind of cottage for the labourer to move into, and advantage can be taken of the process of "moving up" to compel demolition or satisfactory repair of the worst kinds of dwellings.

On the Prevalence of Diphtheria at Ringmer, by Dr. R. J. REECE.[3]—This report relates to a persistent prevalence of diphtheria in a little village in Sussex which appears to have been spread through the agency of the village school and to have continued notwithstanding frequent but short periods of school closure. The account given by Dr. Reece affords one more illustration of the danger of concluding that children are no longer capable of carrying infection because a single examination of a "swab" from the throat has given a negative result as regards the presence of the bacillus diphtheriæ. It also affords a good instance of the way in which apparently healthy children may harbour the diphtheria bacillus in the throat or nose. At the end of September, when the disease had been prevalent in the school for some nine months. Mr. A. G. R. Foulerton made a bacterial examination of swabs from 46 children in Standard I., with the result that the diphtheria bacillus was found to be present in the throat or nasal cavity of 14 of these children. Dr. Reece gives the text of a series of recommendations made to the local authority with a view to check the further spread of the disease: these include the isolation of "infected" and "suspected" cases until they are proved bacteriologically to be free from infection, and the provision of temporary accommodation for the isolation of suspected cases.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8435 births and 5160 deaths were registered during the week ending Dec 21st, 1907, The annual rate of mortality in these towns, which had been 16·0 and 16·1 per 1000 in the two preceding weeks, further rose to 16·8 per 1000 in the week under notice. During the first 12 weeks of the quarter the death-rate averaged 15·7 per 1000, the rate during the same period being 14·9 in London. The lowest death-rates in the 76 towns were 6·0 in Bournemouth, 8·0 in East Ham, 8·7 in Handsworth (Staffs), 9·3 in Hornsey, and 9·9 in Great Yarmouth; the highest rates were 24·1 in Sunderland, 24·2 in Rotherham, 25·6 in Bootle, 25·7 in Tynemouth, 26·0 in Merthyr Tydfil, and 28·9 in Preston. The 5160 deaths in these towns exceeded by 206 the number in the preceding week, and included 398 which were referred to the principal epidemic diseases, against 388 and 374 in the two preceding weeks; of these, 124 resulted from measles, 94 from whooping-cough, 62 from diphtheria, 50 from scarlet fever, 48 from diarrhœa and 20 from "fever" (principally enteric), but not any from small-pox. No deaths from any of these epidemic diseases were registered in Leicester, Blackburn, Brighton, Plymouth, Leyton, Stockport, or in nine other of the 76 towns; the annual rates from these diseases, however, ranged upwards to 3·1 in Aston Manor, 3·3 in Salford, 3·8 in Tynemouth, 4·8 in Rhondda, 5·1 in Barrow-in-Furness, and 8·2 in Bootle. The deaths from measles, which had been 111 and 107 in the two preceding weeks, rose again to 124 in the week under notice. the highest rates being 1·7 in Gateshead, 1·8 in Salford, 1·9 in Leeds, 2·1 in Willesden 3·6 in Rhondda, 3·8 in Tynemouth, and 5·1 in Barrow-in-Furness. The fatal cases of whooping-cough, which had been 107 and 95 in the two preceding weeks, declined to 94. and caused death-rates ranging upwards to 1·1 in Northampton, 1·2 in Rochdale, 1·3 in Sunderland, 1·4 in Ipswich and in King's Norton, 2·5 in Aston Manor, and 4·7 in Bootle. The deaths from diphtheria, which had been 60 and 57 in the two previous weeks, rose again to 62, the greatest proportional mortality being recorded in Handley and in Bootle, where the rate was 1·6 per 1000. The 50 fatal cases of scarlet fever exceeded the numbers registered in any of the seven preceding weeks; the highest death-rate from this disease was 1·0 per 1000 in Burnley. The deaths from diarrhœa, which had been 89, 50, and 47 in the three preceding weeks, were 48 in the week under notice, and caused death-rates ranging upwards to 1·1 in Walsall and 1·4 in Merthyr Tydfil. "Fever" was not excessively fatal in any of the 76 towns. The number of scarlet fever cases under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had been 5676, 5581, and 5352 at the end of the three preceding weeks, had further decreased to 5035 on Saturday, Dec. 21st; 447 new cases were admitted during the week, against 623, 554, and 500 in the three preceding weeks. The deaths in London referred to pneumonia and other diseases of the respiratory organs, which had been 388, 355, and 348 in the three preceding weeks, were 347 in the week under notice, and were 94 below the corrected average number in the corresponding periods of the five years 1902–06 The causes of 36, or 0·7 per cent., of the deaths in the 76 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, and in 56 other towns; six uncertified deaths were registered in London, six in Sheffield, five in Birmingham, five in Liverpool, and two each in Preston, Gateshead, and Rhondda.

---

[2] Ibid., No. 286. Price 4*d*.

[3] Ibid., No. 290. Price 3*d*.

During the week ending Dec. 28th, 5860 births and 4527 deaths were registered in 76 of the largest English towns. The annual rate of mortality in these towns, which had been 16·0, 16·1, and 16·8 per 1000 in the three preceding weeks, declined again last week to 14·7 per 1000. During the 13 weeks of the quarter the death-rate averaged 15·5 per 1000, the rate in London during the same period being 14·9 The death-rates in the 76 towns last week ranged from 6 9 in King's Norton, 7 0 in Hastings, 7·4 in Southampton, and 7·6 in East Ham to 22 8 in Rhondda, 23·5 in Wigan, 23 6 in Ipswich, and 24·4 in South Shields. The 4527 deaths registered in the 76 towns last week were 633 fewer than the number in the previous week, and included 373 which were referred to the principal epidemic diseases, against 374 and 398 in the two previous weeks; of these 373 deaths 105 resulted from measles, 89 from whooping-cough, 71 from diphtheria, 44 from diarrhœa, 41 from scarlet fever, and 23 from "fever" (principally enteric), but not any from small-pox. No deaths from any of these epidemic diseases were registered last week in Hastings, Bournemouth, Reading, Handsworth (Staffs), Smethwick, Coventry, Wallasey, or West Hartlepool; among the other towns the death rates from these diseases ranged upwards to 3·6 in Rhondda, 3·9 in Burton-on-Trent, 4·8 in Tynemouth, and 9·3 in Ipswich. The fatal cases of measles, which had been 107 and 124 in the two preceding weeks, declined again to 105 last week, and caused death-rates ranging upwards to 1·3 in Salford, 1·6 in Bootle, 1·7 in Barrow-in-Furness and in Leeds, 2·7 in Swansea, 2·9 in Burton-on-Trent, 3 8 in Tynemouth, and 7·2 in Ipswich The deaths from whooping-cough, which had been 107, 95, and 94 in the three preceding weeks, further fell to 89 in the week under notice, the highest death-rates from this disease being 1·1 in Northampton, 1 3 in Devonport, in Aston Manor, in Sunderland, and in Newcastle-on-Tyne, 1·4 in Ipswich, and 1·6 in Hanley and in Bootle. The fatal cases of diphtheria, which had been 57 and 62 in the two previous weeks, further rose last week to 71; this disease was proportionally most fatal in Norwich, where it caused a death-rate of 1·3 per 1000. The deaths from diarrhœa, which had been 47 and 48 in the two preceding weeks, declined again to 44 in the week under notice; the mortality from this disease was not excessive in any of the large towns. The fatal cases of scarlet fever, which had been 38, 40, and 50 in the three preceding weeks, fell to 41 last week, and caused death-rates ranging upwards to 1·1 in Walsall, 2·1 in Newport (Mon.), and 2·3 in West Bromwich. The 23 deaths referred to "fever" were three in excess of the number in the previous week, the highest death-rate from this cause being 1·1 in Northampton. There were 4999 scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital at the end of last week, against 5591, 5352, and 5035 at the end of the three preceding weeks; 353 new cases were admitted during the week, against 554, 500, and 447 in the three preceding weeks. The deaths in London referred to pneumonia and other diseases of the respiratory organs, which had been 355, 348, and 347 in the three preceding weeks, further declined to 317 in the week under notice and were 145 below the corrected average number in the corresponding periods of the five preceding years, 1902–06. The causes of 56, or 1·2 per cent., of the deaths registered in the 76 towns were not certified, either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, West Ham, Bradford, Newcastle-on-Tyne, and in 42 other towns; seven uncertified deaths were registered in Liverpool, six in Birmingham, five in Warrington, three in Manchester, and two in each of nine other towns.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been 19·3, 20·6, and 20·0 per 1000 in the three preceding weeks, increased to 20·8 per 1000 during the week ending Dec. 21st, 1907, and was 4·0 per 1000 above the mean rate during the same period in the 76 large English towns. The rates in the eight Scotch towns ranged from 13·7 in Aberdeen and 18 0 in Edinburgh to 27·4 in Leith and 30·5 in Dundee. The 724 deaths in these towns were 28 more than the number in the previous week, and included 126 which were referred to the principal epidemic diseases, against 111, 132, and 127 in the three preceding weeks; of these, 53 resulted from measles, 26 from whooping-cough, 14 from diarrhœa, 11 from diphtheria, seven from cerebro-spinal meningitis, three from scarlet fever, and two from enteric fever. These 126 deaths were equal to an annual rate of 3·3 per 1000, which was 2·0 per 1000 above the mean rate during the same period in the 76 large English towns. The fatal cases of measles, which had been 79 and 71 in the two previous weeks, further declined to 53 in the week under notice, and included 35 in Glasgow, 10 in Dundee, and five in Greenock. The deaths from whooping-cough, which had been 13 and 24 in the two preceding weeks, further rose to 26 of which 11 occurred in Glasgow, four in Edinburgh, four in Aberdeen, three in Perth, and two in Greenock. The fatal cases of diarrhœa, which had been 36, 21, and 18 in the three preceding weeks, further declined to 14 in the week under notice, and included eight in Glasgow and four in Edinburgh. The deaths from diphtheria, which had been nine and eight in the two previous weeks, increased again to 11, of which three occurred in Glasgow, three in Paisley, and two in Leith. Of the seven deaths from cerebro-spinal meningitis three were registered in Glasgow, two in Paisley, and one each in Edinburgh and Leith. The deaths referred to diseases of the respiratory organs, including pneumonia, which had been 167 and 161 in the two preceding weeks, further declined to 157 in the week under notice, but were 38 above the number in the corresponding week of last year. The causes of 25, or 3·5 per cent., of the deaths in the eight Scotch towns were not certified or not stated; in the 76 English towns the proportion of uncertified deaths registered during the same week did not exceed 0·7 per cent.

During the week ending Saturday last, Dec. 28th, the annual rate of mortality in the eight Scotch towns was 18·2 per 1000, against 20·6, 20 0, and 20 8 per 1000 in the three preceding weeks, and was 3·5 per 1000 above the mean rate last week in the 76 large English towns. Among the Scotch towns the death-rates ranged from 12·5 in Leith and 13·2 in Aberdeen to 24·2 in Greenock and 25·4 in Perth. The 632 deaths registered in these towns last week were 92 fewer than the number in the preceding week, and included 109 which were referred to the principal epidemic diseases, against 132, 127, and 126 in the three preceding weeks; of these 53 resulted from measles, 24 from whooping-cough, 14 from diarrhœa, seven from diphtheria, five from scarlet fever, three from enteric fever, and three from cerebro-spinal meningitis, but not any from small-pox. These 109 deaths were equal to an annual rate of 3 1 per 1000, which was 1·9 per 1000 above the mean rate last week from the principal epidemic diseases in the 76 large English towns. The fatal cases of measles, which had been 79, 71, and 53 in the three preceding weeks, were again 53 last week, and included 22 in Glasgow, eight in Dundee, four in Greenock, and two in Aberdeen. The deaths from whooping-cough, which had been 13, 24, and 26 in the three preceding weeks, declined again last week to 24, of which six occurred in Glasgow, six in Perth, three in Edinburgh, three in Dundee, three in Leith, and two in Greenock. The fatal cases of diarrhœa, which had been 21, 18, and 14 in the

the first proceeding necessary is to treat derelict tenement blocks, jet factories, and warehouses as obstructive buildings under the Housing of the Working Classes Act, with a view to letting in light and air to the remaining blocks. This could be done, Dr. Farrar notes, "without seriously impairing the effect of the huddle of red roofs which is one of the æsthetic charms of Old Whitby." The space thus gained could be utilised as *open space in a variety of useful ways*, and the authorities concerned should then use their powers to secure that the remaining blocks are put into habitable repair. Along with these measures it is desirable that a certain number of modern working-class dwellings should be erected. *Action by the district* council on these lines has been successfully taken at Alnwick and other old towns presenting similar problems. The district council, in the *hope of re*habilitating the ship building and fishing industry of Whitby, is proposing to spend no less than £95,000 on harbour extensions and improvements and on the rebuilding of Whitby bridge. If the anticipation of increased prosperity is justified it will be *essential to provide for increase* in, and improvement of, the house accommodation which is available for the working-class population. If the anticipation is unlikely to be justified (and in view of recent extensions of competing ports the proposal seems open to some doubt) the Whitby council would probably be serving its town better by abandoning grandiose schemes and by spending a much more moderate sum on housing improvements which at least may be relied upon to yield a return in the form of the better health and physical conditions of the population.

On the Sanitary Circumstances and Administration of the Thingoe Rural District, by Dr. F. ST GEORGE MIVART [2]—Many interesting matters are dealt with in this report which relates to a large rural district with some 14 000 inhabitants *surrounding the borough of Bury St. Edmunds.* Among these are the insanitary conditions of dairy farms, many of which supply London dairy companies, and the unsatisfactory conditions of housing which prevail. The want of more cottages is "bitterly felt" in this district, and this is little to be wondered at in view of the character of many of those which now exist. Dr. Mivart reports that often houses were in a ruinous condition, the holes in the plaster walls being plugged with old sacks and rags within or blocked with a piece of plank and odds and ends of timber without. Such houses were also leaky in other places—e.g., round the door and window frames, and occupiers resort to all sorts of *expedients to prevent* the entrance of cold air in winter. Rain-water pipes when present are commonly broken and while allowing the water to stream down the house walls deliver it also upon the ground in proximity to foundations, the surface about the house being only in a few instances furnished with paving. *As to cottage* bedrooms the report points out that sometimes the first-floor space comprises two or three rooms, of which the back one has no direct supply of light and air at all. The following account of a cottage in Sicklesmere is given as an instance of the use to which first-floor space may be put without bringing about prosecution for overcrowding:—"*Total first-floor space, about* 13 × 15 × 7 feet = about 1365 cubic feet of space. A corner of this, sufficient to hold a bed, is screened off by a dwarf partition about 4 feet 6 inches high. The entire first-floor space is shared by six persons, viz., a widow, aged 40; two sons, aged 16 and 14; two daughters, *aged 13 and 6; and, as a lodger,* a brother-in law, aged about 50. No fireplace or back window. Ventilation only by front window 2 feet square and by the opening in the floor for the ladder staircase." In the living rooms the fireplaces are often so poor that "cooking of any useful kind would be almost *impossible even* if inmates had sufficient knowledge for this." Many cottage dwellings are going steadily to ruin There is special difficulty in getting repairs in "tied" cottages—i.e., those rented by the farmers for their labourers. It is sometimes said that stringency of building by-laws prevents building in rural areas, but in this district no by-laws as to new buildings are in force. It should be said, however, that the district council made an attempt some years ago to utilise the Housing of the Working Classes Act. Eight good semi-detached cottages in *four blocks, with* sufficient land, were erected at Ixworth in 1893 at a cost of £1700, obtained by loan repayable in 30 years. The innovation was subjected to much local criticism and ridicule under the name of the "Thingoe Folly." But Dr. Mivart found the houses all occupied; he gives the profit and loss account in connexion with them, and shows that when the loan is extinguished the council is likely to find itself well on the right side of the account. The experiment suggests that subject to some alterations, such as lengthening the borrowing period, it would be practicable to do much good by similar "follies" in other villages and hamlets. Too much stress must not be laid on the argument that properly built cottages of this kind must be let at a higher rent than the labourer can afford. *Those who can afford* the rent and go into these cottages in most cases vacate a better kind of cottage for the labourer to move into, and advantage can be taken of the process of "moving up" to compel demolition or satisfactory repair of the worst kinds of dwellings.

On the Prevalence of Diphtheria at Ringmer, by Dr. R. J. REECE [3]—This report relates to a persistent prevalence of diphtheria *in a little village in Sussex which appears to* have been spread through the agency *of the village school* and to have continued notwithstanding *frequent but short* periods of school closure. The account given by Dr. Reece affords one more illustration of the danger of concluding that *children* are no longer *capable* of carrying infection because a single examination of a "swab" from the throat has given a negative result as regards the presence of the bacillus diphtheriæ. It also affords a good instance of the way in which apparently healthy children may harbour the diphtheria bacillus in the throat or nose. At the end of September, when the disease had been prevalent in the school for some nine months, Mr. A. G. R. Foulerton *made* a bacterial examination of swabs from 48 children in Standard I., with the result that the diphtheria bacillus was found to be present in the throat or nasal cavity of 14 of these children. Dr. Reece gives the text of a series of recommendations made to the local authority with a view *to check the further* spread of the disease; these include the isolation of "infected" and "suspected" cases until they are proved bacteriologically to be free from infection, and the provision of temporary accommodation for the isolation of suspected cases.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8435 births and 5160 deaths were registered during the week ending Dec 21st, 1907, The annual rate of mortality in these towns, which had been 16·0 and 16·1 per 1000 in the two preceding weeks, further rose to 16·8 per 1000 in the week under notice. During the first 12 weeks of the quarter the death-rate averaged 15·7 per 1000, the rate during the same period being 14·9 in London. The lowest death-rates in the 76 towns were 6·0 in Bournemouth, 8·0 in East Ham, 8·7 in Handsworth (Staffs), 9·3 in Hornsey, and 9·9 in Great Yarmouth; the highest rates were 24·1 in Sunderland, 24·2 in Rotherham, 25·6 in Bootle, 25·7 in Tynemouth, 26·0 in Merthyr Tydfil, and 28·9 in Preston. The 5160 deaths in these towns exceeded by 206 the number in the preceding week, and included 398 which were referred to the principal epidemic diseases, against 388 and 374 in the two preceding weeks; of these, 124 resulted from measles, 94 from whooping-cough, 62 from diphtheria, 50 from scarlet fever, 48 from diarrhœa and 20 from "fever" (principally enteric), but not any from small-pox. No deaths from any of these epidemic diseases were registered in Leicester, Blackburn, Brighton, Plymouth, Leyton, Stockport, or in nine other of the 76 towns; the annual rates from these diseases, however, ranged upwards to 3·1 in Aston Manor, 3·3 in Salford, 3·8 in Tynemouth, 4·8 in Rhondda, 5·1 in Barrow-in-Furness, and 6·2 *in Bootle.* The deaths from measles, which had been 111 and 107 in the two preceding weeks, rose again to 124 in the week under notice, the highest rates being 1·7 in Gateshead, 1·8 in Salford, 1·9 in Leeds, 2·1 in Willesden 3·6 in Rhondda, 3·8 in Tynemouth, and 5·1 in Barrow-in-Furness. The fatal cases of whooping-cough, which had been 107 and 95 in the two preceding weeks, declined to 94, and caused death-rates ranging upwards to 1·1 in Northampton, 1·2 in Rochdale, 1·3 in Sunderland, 1·4 in Ipswich and in King's Norton, 2·5 in Aston Manor, and 4·7 in Bootle. The deaths from diphtheria, which had been 60 and 57 in the two previous weeks, rose again to 62, the greatest proportional which is equal to the entire loss of the service of 384 men for the year.

"Audi alteram partem."

LORD KELVIN AND PUBLIC HEALTH.

To the Editor of THE LANCET.

SIR,—A service which Lord Kelvin rendered to public health a few years ago perhaps deserves reference at a time when much is being written about his many activities. When it was decided to appoint a Royal Commission after the occurrence of poisoning on a large scale by arsenic in beer in Manchester in 1900 Lord Kelvin was asked by Mr. Walter Long, then President of the Local Government Board, to be its chairman. The inquiry was certain to be—as it proved—lengthy and in several respects tedious. The subject, save that it called for ability to master a variety of complicated scientific and technical considerations, was far out of Lord Kelvin's ordinary lines, and at the age of nearly 60 he might well have hesitated to burden himself with it. But the request of the Government was sufficient; he acceded to the proposal, if I remember right, by return of post, and during 1901 and 1902 he presided over nearly all of some 35 sittings (many of which occupied the greater part of a day) in London and Manchester. It is generally recognised that the work done by the Commission under his guidance has had valuable results. Its final report has become the recognised authority for the various manufacturing and brewing industries and also for the administrative bodies which are concerned with the question of arsenical poisoning through food, while its more general recommendations have had an important share in determining recent Government action to secure improved methods of control in regard to impurities and deleterious substances in foodstuffs, as exemplified by Mr. Burns's Regulations as to Food Act of last session.

Many of those who were concerned with the work of the Commission will retain pleasant recollections of Lord Kelvin's interest and active assistance and a vivid memory of the mental alertness and power of concentration which in him was so strong a characteristic.

I am, Sir, yours faithfully,

London, Dec. 21st, 1907. G. S. BUCHANAN.

ON A SYMPTOM WHICH OCCASIONALLY MAY THROW LIGHT ON THE DIAGNOSIS OF MOVEABLE KIDNEY.

To the Editor of THE LANCET.

SIR,—The interesting communication of Dr. Hector Mackenzie on Mobility of the Kidneys which appeared in THE LANCET of Oct. 26th, 1907, takes in all that is known on the subject, in my opinion. As regards the symptomatology, the statement of the author, when he says, referring to the greater part (411 in 515) of the cases which have come under his observation, that they "had no symptoms which with any reasonableness could be attributed to the condition of the kidneys," expresses exactly the truth contained in the words of Professor Osler therein quoted, namely, "that in the majority of the cases ('in a vast majority,' says Dr. Mackenzie) there are no symptoms whatever."

As a matter of fact, the epigastric pain mentioned by Edebohls as characteristic, the different manifestations of dyspepsia, the vomiting crises described by Dietl, and the different neurotic affections, such as migraine, vertigo, neuralgia, hypochondriasis, epilepsy, neurasthenia, &c., have not been established in cases of mobility of the kidneys with the frequency necessary to prove clearly a connexion between such phenomena and the anatomical derangement in question. Even a certain amount of irritability of the bladder with an irresistible desire to pass urine, which I have observed sometimes, and which is pointed out in Dr. Mackenzie's communication, I have been led to recognise by the further development of the case as a manifestation of cirrhotic interstitial derangements of the gland concomitant with the relaxation of the organs which sustain it rather than being symptomatic of moveable kidney. The sensation of a lump in the lower part of the abdomen near the hip, so long as the nature of the tumour be not defined, is without any pathognomonic significance. I have seen patients who have complained that something is trying to escape from the belly through the groin when they run, cough, or lift heavy objects, and one was already wearing a truss when he came to consult me.

It has been in such cases that I have been able to observe a symptom which I consider to be of real use in the diagnosis. It is the following. In persons habitually constipated, or who have to make great exertion at the time of defæcation, it happens that when they are emptying or beginning to empty the bladder they experience a sharp cruel pain which stops the flow of the urine and runs through the urinary passages with all the characteristics of nephritic colic. Instinctively the patient changes his position, rises from his seat, and puts his hand on the lower part of the belly, pressing or rubbing the side affected; by doing which the pain disappears with the same suddenness as that with which it came on, urination goes on, and everything proceeds in due course. The mechanism of the phenomenon seems to be explained either by a compression of the kidney caused by the effort to evacuate or by a sudden obstruction of the ureter by excessive twisting or distension and its disappearance by the cessation of the circumstances mentioned, due to the movements of the patient. Having regard to an affection which may easily pass unperceived from want of subjective phenomena, I think that it is of use to point out any which, even occasionally, may serve to make it recognisable.

On this understanding I have ventured to take up a small space in your columns, adding, in conclusion, that the pain to which I refer must have, in order to be regarded as a symptom of moveable kidney, the following feature: (1) a sudden appearance at the time of great exertion, chiefly during defæcation and while the patient is passing urine; (2) that the pain should be felt along the urinary passages as in nephritic colic and with sufficient intensity to interrupt urination; and (3) instantaneous disappearance on change of position of the patient or light massage on the side of the abdomen affected. It is, of course, clearly understood that renal lithiasis may make itself felt in the act of defæcation, but the differentiation between such lithiasis and moveable kidney would be so easy that I do not think it necessary to point it out.

I am, Sir, yours faithfully,

Zacatecas, Mexico. JUAN BRENA, M.D.

THE MICROSCOPE IN WAR.

To the Editor of THE LANCET.

SIR,—I have read with much interest the chairman's address to the Swansea division of the British Medical Association[1] but, while sympathising with Dr. J. Arnallt Jones's desire to popularise the study of bacteriology amongst general practitioners, I venture to join issue with his opinion as to the rôle of the microscope in war. Dr Jones says that "Major Seaman of the U.S. Army in his report pointed out that the Japanese medical officer was invariably found in the first screen of scouts with his microscope and chemical reagents testing and labelling wells so that the army following should drink no contaminated water." This might be accepted by an audience unacquainted with the conditions of military service but I do not think that the members of the medical department of any army will agree with the medical officer of health of Aberavon that it is "a brilliant practical illustration" of "what science can do in the way of preventing disease in war."

If Dr. Jones will refer to the Parkes Memorial Prize Essay for 1904 he will find that Lieutenant-Colonel Robert Caldwell, R.A.M.C., who has had great experience, writes as follows: "It does not appear likely that the introduction of a chemical laboratory into the field is likely to be followed by any particular benefit. An incomplete analysis is valueless; it tells of danger but cannot tell of safety, and it is impossible to carry out any analysis but an incomplete three preceding weeks, were again 14 in the week under notice, and included five in Glasgow, three in Aberdeen, two in Edinburgh, two in Dundee, and two in Paisley. The deaths from diphtheria, which had been eight and 11 in the two preceding weeks, declined last week to seven, of which four were registered in Glasgow. The fatal cases of scarlet fever, which had been three in each of the two previous weeks, rose last week to five, and included three in Glasgow, where the three deaths from cerebro-spinal meningitis also were registered. The deaths referred to diseases of the respiratory organs in these eight towns, which had been 167, 161, and 157 in the three preceding weeks, further fell to 127 in the week under notice and were 40 below the number in the corresponding period of last year. The causes of 26, or 4·1 per cent., of the deaths in these towns were not certified or not stated; in the 76 English towns the proportion of uncertified deaths was 1 2 per cent.

---

[1] Brit. Med. Jour., Dec. 21st, 1907, p. 1764.

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been 26·7 and 22·3 per 1000 in the two preceding weeks, rose again to 25·0 per 1000 in the week ending Dec. 21st, 1907. During the first 12 weeks of the current quarter the death-rate averaged 21·7 per 1000, the rate during the same period being 14·9 in London and 14·4 in Edinburgh. The 187 deaths of Dublin residents registered during the week under notice were 20 in excess of the number in the previous week, and included ten which were referred to the principal epidemic diseases, against four, nine, and six in the three preceding weeks; of these, four resulted from diarrhœa, three from diphtheria, two from whooping-cough, and one from scarlet fever, but not any from small pox, from measles, or from "fever." These ten deaths were equal to an annual rate of 1·3 per 1000, the death-rates during the same week from the principal epidemic diseases being 1 0 in London and 1·4 in Edinburgh. The four fatal cases of diarrhœa exceeded the numbers in the three preceding weeks; the three deaths from diphtheria corresponded with the number in the previous week. The 187 deaths from all causes in Dublin during the week under notice included 40 of children under one year of age and 53 of persons aged upwards of 60 years; these numbers were respectively 13 and five in excess of the corresponding numbers in the previous week. Eight inquest cases and six deaths from violence were registered; and 78, or 41·7 per cent., of the deaths occurred in public institutions. The causes of four, or 2·1 per cent., of the deaths registered in Dublin during the week were not certified; in London the proportion of uncertified deaths was 0·4 per cent., while in Edinburgh the proportion was not less than 9·2 per cent. of the total deaths.

In the week ending Dec. 28th the annual rate of mortality in Dublin was 19·8 per 1000, against 22·3 and 25·0 per 1000 in the two preceding weeks. During the past 13 weeks the death rate has averaged 21·5 per 1000, the rates during the same period being 14·9 in London and 14·6 in Edinburgh. The 148 deaths of Dublin residents registered last week were 39 fewer than the number in the three preceding week, and included five which were referred to the principal epidemic diseases, against nine, six, and ten in the three preceding weeks; of these, two resulted from whooping-cough, one from scarlet fever, one from diphtheria, and one from "fever," but not any from small-pox, measles, or diarrhœa. These five deaths were equal to an annual rate of 0·7 per 1000, the death-rates last week from the principal epidemic diseases being 0 9 in London and 1·1 in Edinburgh. The 148 deaths from all causes in Dublin included 25 of children under one year of age and 38 of persons aged upwards of 60 years; the deaths both of infants and of elderly persons showed a decline of 15 from the respective numbers recorded in the previous week. One inquest case and two deaths from violence were registered, and 54, or 36·5 per cent., of the deaths occurred in public institutions. The causes of three, or 2·0 per cent., of the deaths in Dublin last week were not certified; in London only two of the 1326 deaths were uncertified, while in Edinburgh the proportion was 4 5 per cent. of the total deaths.

WEST LONDON POST-GRADUATE COLLEGE.—The next session of this College will commence on Monday, Jan. 13th, and will last for 12 weeks.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

IN accordance with the provisions of Her late Majesty's Order in Council of April 1st, 1881, Fleet-Surgeon William Gordon Stott has been placed on the Retired List at his own request (dated Dec. 29th, 1907). Inspector General of Hospitals and Fleets John Cassilis Birkmyre Maclean has been placed on the Retired List at his own request (dated Dec. 31st, 1907).

The following promotions have been made: Deputy Inspector-General of Hospitals and Fleets William Edward Breton to be Inspector-General of Hospitals and Fleets in His Majesty's Fleet, and Fleet-Surgeon Frederick John Lilly to be Deputy Inspector-General of Hospitals and Fleets in His Majesty's Fleet (dated Dec. 31st, 1907).

The following appointments are notified: Fleet Surgeon: H. F. Illewicz to the *President*, additional, for three months' course at the London and West London Hospitals. Staff Surgeon: M. Cameron to the *Indefatigable*, additional, and on recommissioning. Surgeon: J. N. Robertson, to the *President*, additional, for three months at West London Hospital.

ROYAL ARMY MEDICAL CORPS.

Captain H. A. Bransbury has been appointed to the London District. Captain A. O. Osburn, from Agra, has been transferred to the Burmah Division for duty.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Major Robert B. Graham to be Surgeon-Lieutenant-Colonel (dated Dec. 17th, 1907).

ROYAL ARMY MEDICAL CORPS (VOLUNTEERS).

Eastern Command: Woolwich Companies: Lieutenant-Colonel and Honorary Colonel Francis Lawrence Stephenson, C B., retired (lately Commanding), is appointed to the Honorary Colonelcy of the Companies, vice Surgeon-Lieutenant-Colonel W. Collingridge, retired (late Militia Medical Staff Corps), who vacates that appointment (dated Oct. 16th, 1907).

THE HEALTH OF THE UNITED STATES NAVY.

The statistical report of the health of the Navy and Marine Corps for the year 1906 shows that the average strength of the active list during the year was 42 529, an increase of 1316 over the previous year, the average strength of 1905 being 41,313. The total number of admissions to hospital for all causes was 32,517, the ratio per 1000 of strength being 787·23, as compared with a ratio of 714·81 for the previous year and 788·18 for the ten preceding years. There were 27,452 admissions for disease and 5065 for injuries, giving ratios of 658 47 and 121·49 respectively. The corresponding ratios for 1905 were 594·82 and 106 67, from which it will be seen that the admissions for diseases and injuries were greater than in 1905. The number of persons invalided from the service during the year for disease and injury was 1117, giving a ratio of 26·26 per 1000 of strength. The corresponding figures for the previous year were 1201 and 29·07 respectively. The ratio for 1906 is lower than that for last year and of the ten preceding years. The discharges for disability include 908 for disease and 209 for injury, with ratios per 1000 of strength of 21 35 and 4 91 respectively. The corresponding figures for 1905 were 1023 and 4·38, with ratios per 1000 of strength of 24 76 and 4·38 respectively. There were 241 deaths during the year, giving a ratio of 5 66, which is considerably less than that of the previous year (6·48) and less than the average of the ten preceding years (6·63). The diseases causing the largest number of admissions to the sick list stand in the following order: gonorrhœa, 2640; malarial diseases, 1854; tonsillitis, 1375; bronchial affections, 1211; wounds, 1211; syphilis, 1147; epidemic catarrh, 1076; and rheumatic affections, 980. Venereal diseases caused a decided loss of efficiency, with 7273 admissions, which is an increase of 1119 over the admissions for 1905 The admissions for these diseases show only approximately the prevalence of venereal infection in the navy, owing to the fact that a large number of cases of chancroid, and especially of gonorrhœa, are not admitted to the sick list, and hence are not included in the statistical reports. Venereal diseases give a total of 140,352 sick days,

THE GENERAL HOSPITALS AND THE TRAINING OF MIDWIVES.

To the Editor of THE LANCET.

SIR,—In commenting on the report of a meeting recently convened by the Association for Promoting the Training and Supply of Midwives, the *Times* in a leading article expressed regret that none of the speakers, beyond urging the necessity for increased support of the Association, gave any indication as to the means by which the serious difficulty is to be met which may arise in 1910 when the clauses in the Act forbidding the practice of midwifery by unqualified persons come into operation. The opinion was also expressed that "a very definite organisation with definite and clearly stated aims is a necessary condition of any extended support from the public." A subsequent letter from the Council of the Association makes the issue clear—viz., which is to come first, the plan or the money?

I am writing in the hope that the suggestions contained in this letter may help the Association to a decision upon this point. I cannot claim to speak with any authority on the general question, but I have been led during the past two years to take an interest in it owing to my appointment as a visitor of some of the lying-in hospitals of London by the Council of King Edward's Hospital Fund. No one can enter the wards of one of these hospitals without being struck with the enormous advantage which any poor woman whose labour is conducted there enjoys over her less fortunate sister who is confined in her own home, often amidst surroundings which can only be realised by those who have actually witnessed them. It is gratifying to learn that by the adoption of a rigidly aseptic and antiseptic method maternal mortality has in these institutions been practically abolished. It is equally saddening to reflect that whilst the lying-in ward has been transformed from a death-trap to a place of the greatest attainable safety, there has been little or no diminution in the mortality from child-birth throughout the country generally.

The Faculty of Medicine of the University of London was recently asked by the Senate to advise as to the action to be taken by the University upon the proposed regulation of the General Medical Council that every student shall be required to have received instruction and gained his practical knowledge of midwifery by attending the requisite number of labours, either in a lying-in hospital or in the lying-in ward of a general hospital. I am glad to say that a resolution was passed that in the opinion of those present "teaching in practical midwifery in the wards of a lying-in hospital or in the lying-in ward of a general hospital should be made compulsory as soon as practicable."

I lately suggested to the Weekly Board of the Middlesex Hospital that a lying-in ward should be established, so that our students may learn this most important branch of their profession under the best possible conditions and not, as hitherto, by attendance upon the poor living in the area supplied by the hospital. The suggestion received the approval of the board and of the medical staff and a committee is about to report upon the changes necessary to carry it into effect. The existence of such a ward is no new thing, as in 1747 it was enacted that "a third part of the beds used in the hospital from time to time be appropriated to the use of lying-in women." The total number of beds in the hospital at that date was either 18 or 22. In 1749 a rule was established that "whenever there shall be an increase of beds for sick and lame the same number be also added for lying-in women." In 1763, owing to lack of funds, retrenchments became necessary and these were continued at intervals until 1807, when the lying-in ward was abolished.

Such a ward in a general hospital to which a medical school is attached would serve a fourfold purpose: 1. It would insure that a certain number of poor women were delivered under conditions involving in a normal pregnancy the minimum risk to life. 2. The offspring would be free from the danger of contracting purulent ophthalmia, which two of the speakers at the meeting referred to stated to be the cause of fully one-fourth of the cases of blindness in the community to-day. 3. It would afford the students an opportunity of learning thoroughly the aseptic and antiseptic technique of modern midwifery, knowledge which must in their future practice be of the greatest service to them and therefore to the public. 4. It would allow the hospital to become a centre for the training of nurses skilled and certificated in midwifery and thus increase its claims to public support. Some of these nurses might be available for attendance upon the poor living in the neighbourhood of the hospital, thus replacing the services of the students.

I would therefore suggest to the Association that it should forthwith institute a campaign throughout the country to urge: 1. That every general hospital should as soon as possible provide a lying-in ward. 2. That the general hospitals in each county should become centres for the instruction of midwives, who would obtain there the certificates necessary to secure admission to the Roll. 3. That one or more branches of the association should be established in each county in connexion with the general hospitals in order to ascertain and provide for the wants of the county as regards midwives and to organise and to supervise their work. 4. That the county councils and local authorities should exercise the powers given to them by the Act of making grants towards the cost of the education given to midwives in the hospitals; thus the whole community would bear a part of the expense to which the hospitals would be put in carrying this proposal into effect and not only those members of it who recognise their duties to the poor.

I venture to submit these suggestions as the basis of a scheme which may provide "the definite organisation with clearly stated aims" necessary to secure increased public support of the Association. I have not referred to the good work which I know Queen Charlotte's Lying-in Hospital is doing in increasing the provision for the instruction of students, as the need is for a scheme applicable to the country as a whole.

I am, Sir, yours faithfully,
J. K. FOWLER,
Dean of the Faculty of Medicine, University of London.
Clarges-street, W., Dec. 28th, 1907.

THE COEFFICIENT OF DISINFECTANTS AS REGARDS THE PLAGUE BACILLUS.

To the Editor of THE LANCET.

SIR,—The statements made with reference to the coefficient of various disinfectants against the bacillus pestis indicate that this organism is particularly susceptible to the influence of the various preparations used for disinfecting purposes, but I gravely doubt whether all these statements are absolutely reliable. My reason for saying this is based upon the results of a series of experiments made when examining a well-known disinfectant. I found that using broth for cultivating purposes, with and without the addition of a little butter, the results were sometimes doubtful. I therefore made from all the tubes giving no definite indications of growth agar slope cultures and was not surprised to find after several days that a distinct growth of the bacillus pestis made its appearance. The result was that the disinfectant under trial gave a coefficient about the same as that obtained when the bacillus typhosus was used, whereas judging from the broth cultures alone it was nearly twice as high. An attempt was made to use agar slopes in the first instance instead of the broth, but the results then differed widely from those obtained either with broth alone or with broth followed by agar. Probably other bacteriologists interested in this subject may care to repeat my experiments and confirm or disprove my results. This is my excuse for troubling you with this letter.

I am, Sir, yours faithfully,
JOHN C. THRESH, M.D. Vict., &c.
London Hospital Medical College, Dec. 23rd, 1907.

TWINS: A CURIOUS INCIDENT.

To the Editor of THE LANCET.

SIR,—At Stoke Newington recently inquests were held upon the bodies of twin boys, aged 18 months, who were found dead at the same time in the same bed on a Friday afternoon about 6 P.M. One child had been brought up by the bottle on cow's milk and barley water and the other had been suckled. Both had seemed well until the Sunday before, when both became poorly with colds in the head and coughs. The mother treated the children with castor-oil and embrocations of camphorated oil. She did not think either was seriously ill until the Friday, when one was taken to a doctor who prescribed for it at noon; the other had no medical attendance. The parents declared that both had one under the conditions of active service, and for this reason any such attempt should be abandoned. Water (water being naturally the main subject for analysis) might, for instance, give excellent results when examined chemically and might at the same time be swarming with an extensive variety of disease-producing germs. These latter could not possibly be detected without recourse to appropriate bacteriological methods and such methods could only find practical application within the walls of a properly equipped laboratory."[2]

During the recent autumn manœuvres in Wiltshire the writer of the foregoing, in his capacity as sanitary officer of the Northern Army, took samples of water from the River Wyley both before and after it had passed through the new army water-cart. The samples reached the District Laboratory, Devonport, the day following their despatch. I was in temporary charge of the laboratory during Colonel Caldwell's absence and examined them for the presence of bacillus coli communis according to the method recorded by Dr. Thresh in his admirable work on "Water and Water-supplies" (p 351). The river water gave unmistakeable evidence of bacillus coli in so low a dilution as one cubic centimetre, whereas 20 cubic centimetres of the water which had passed through the service cart showed no evidence of coliform organisms. The chemical constituents of both samples were within the limit prescribed for "a good potable water." This bears out Colonel Caldwell's opinion, as expressed above, that incomplete or chemical examinations of water are valueless and shows, I think, that if the Japanese medical officer was actually "with the first screen of scouts analysing water and labelling wells" his labours were sad waste of energy and his "labels" not worth the paper they were written on.

In conclusion, I venture to predict that the microscope will perform an important rôle in the wars that are to come but it will be neither "with the first line of scouts" nor in the stress of the fighting line, but in the properly equipped laboratories which the sanitary section of the expeditionary forces of the future will establish at their base and on their lines of communication.

I am, Sir, yours faithfully,

R. J. Blackham,

Devonport, Dec. 23rd, 1907. Major, Royal Army Medical Corps.

A PLEA FOR THE SIMPLE METHOD OF DRAINING THE BLADDER AFTER SUPRAPUBIC CYSTOTOMY.

To the Editor of The Lancet.

Sir,—In the large mass of recent literature on the subject of the most satisfactory method of draining the bladder after suprapubic cystotomy the simplest and best method of all, by what may be called natural syphon action, appears to have been temporarily forgotten. The method I have been in the habit of using in such cases for some time past has the merit of simplicity and efficiency and is briefly as follows. The incision in the bladder wall is reduced in size by a series of strong catgut sutures, introduced on the Lembert principle, until only a sufficient opening is left to take a large drainage-tube. Two holes are cut on opposite sides of the lower end of this tube which is placed well down on to the trigone or into the cavity from which a prostate has been removed. The long end projects from the wound and the tube is fixed in the opening in the anterior wall of the bladder by a purse-string catgut suture, one portion of which transfixes the tube to still further secure it in position. The skin incision is left widely open and the connective tissue space around the bladder, which has been opened up in the course of the operation, is carefully but lightly packed with sterilised gauze. When the patient has been put back to bed a long narrower rubber tube is attached to the tube in the bladder, and then runs over the side of the bed into a bottle or other vessel containing dilute lysol solution, the end of the tube naturally being below the level of the fluid. The syphon thus formed starts to work of itself and in my experience answers admirably. It is important to take care that the purse-string suture produces a good funnel-shaped projection of bladder wall round the tube and to test the efficacy of the closure of the bladder by distending the cavity with fluid, passed into the bladder by means of a soft catheter by the urethra, before the operation is completed. The bladder may be washed out in the same way after the operation if necessary, but usually the drainage is so perfect that it is only in advanced cases of bilharziosis, or cystitis from any other cause, that this will be required. The tube is left in from four to eight days and on its removal the bladder is washed out from time to time by the urethra. A few days later the bladder has dropped back well into its place and the wound in it is firmly healed. It is a great mistake, in my opinion, to attempt to suture the bladder wall to the skin or deeper tissues, as this procedure is so often followed by a very intractable sinus. Once the tube has been removed the patient should be allowed to sit up and two days later to walk, as both these actions tend to drive the urine, so to speak, out of the bladder by its natural channel. The rather special opportunities one has in the practice of bladder surgery in Egypt must be my apology for venturing to trespass on your space to this extent and the feeling that, perfect as some of the more complicated methods appear to be, they are rather unnecessary in view of the simpler measures which are at our disposal.

I am, Sir, yours faithfully,

Cairo, Dec. 3rd, 1907. Frank C. Madden.

ACUTE PULMONARY ŒDEMA.

To the Editor of The Lancet.

Sir,—The interesting communications under this title have drawn attention to a condition which, though familiar, is not often described. It should, however, be kept distinct from acute suffocative catarrh, a condition well described by Laennec, but not, it would seem, generally recognised now any more than it was at the time he wrote. To the description Laennec gave, little, if anything, can be added. Dyspnœa comes on suddenly, rapidly becomes intense, and in a few hours the patient may die from suffocation. If life be prolonged the condition becomes one of ordinary bronchial catarrh. Laennec's suffocative catarrh has to be distinguished from capillary bronchitis and disseminated post-bronchitic broncho-pneumonia, for in these cases the suffocative symptoms are secondary. More closely resembling it are primary broncho-pneumonia—i.e., disseminated pneumococcal broncho-pneumonia and possibly an acute pneumococcal or other bacterial bronchitis. In association with it may be placed: 1. Cases of acute pulmonary œdema which develop in the course of chronic heart obstruction or of acute heart failure, such as most of those are which have been recently described. 2. Cases of collateral fluxion or pulmonary failure such as are familiar in the course of acute pneumonia in the non-consolidative parts of the lung. 3. An interesting but not common group of cases in which acute pneumonia commences with widespread pulmonary congestion, the general congestion disappearing as the local lesion develops.

I write this as a preliminary note, for I propose to bring the whole subject shortly before one of the medical societies. It has been stated that no account of these conditions appears in the ordinary text books. The various conditions I have referred to are, however, all discussed in my book on "Diseases of the Respiratory Organs," and I daresay elsewhere too.

I am, Sir, yours faithfully,

Dec. 30th, 1907. Samuel West.

To the Editor of The Lancet.

Sir,—The clear clinical picture of "Acute Pulmonary Œdema," drawn by Dr. Leonard Williams in The Lancet of Dec. 7th, 1907 has left an impression on my mind which will never be effaced. Although the condition is one of great rarity, doubtless its occurrence is much more frequent than is generally supposed, being overlooked by the fact that no description of it is to be found in any of our English text-books, and hence students have not been made familiar with the symptoms. I can certainly recall a case in which, although a fatal issue was not unlooked for, I was yet unable to account for the long stream of foam issuing from the mouth and nose, and have now no doubt that the actual cause of death was acute œdema of the lungs. The omission of such an important mode of death from our English text-books, and also I notice from the ' Nomenclature of Diseases" issued by the Royal College of Physicians of London, is much to be regretted, and one can only hope that it will be repaired at an early date.

I am, Sir, yours faithfully,

Alexander Bryce, M D. Glasg., D.P.H. Cantab.

Moseley, Birmingham, Dec. 26th, 1907.

---

[2] Prevention of Disease in Armies in the Field, p. 149.

the baker, the dressmaker, the draper, the landlord, the tailor, and other tradesmen. The objects of the Act would have been more fully accomplished had it empowered local authorities to grant a moderate fee to any licensed practitioner who attended a case of confinement in circumstances precluding any hope of any other recompense. The present Government seems inclined to pass enactments to ameliorate the condition of the masses, and if any of its measures would make it impossible for anyone to spend in drinking, betting, and smoking the money that should be spent in supplying himself or herself and dependents with the necessaries of life the above Act and many others would never have been required. Until restrictions are put on these three bad habits, so that no one could spend more than a certain amount on either of them—the amount allowed to be limited to income and obligations—all other ameliorative measures will be comparatively useless. Slavery has been abolished in the British dominions, but there are still a great many people who would be better to be still in slavery under a kind master. They are quite unworthy of their freedom and cannot enjoy it properly, and if the present Government passes restrictive measures to prevent these unworthy people from injuring themselves, their dependents, or the community generally, then others who need no such restrictions should cheerfully acquiesce in the new arrangements for the sake of their weaker brethren. It is hoped and expected that Parliament, soon to assemble, will put restrictions on these three great evils.

I am, Sir, yours faithfully,

JOHN B. HUNTER, M.D., C.M. Glasg.

Paisley, Dec. 25th, 1907.

PS.—It is certainly an outrage on humanity and a disgrace to civilisation that a poor woman in labour cannot command skilful attention in her dire distress.

THE MEDICAL INSPECTION OF SCHOOL CHILDREN.

To the Editor of THE LANCET.

SIR,—I should be much obliged if your readers in other parts of the country would favour the medical profession with information as to how their county councils are going to carry out the medical inspection of school children. Are they going to appoint whole-time medical inspectors specially for this purpose or are they going to intrust the work to be done to general practitioners? It appears to me that the claims of the latter are being overlooked in the matter and that the county councils, in appointing a special staff wholly for this work, are embarking on an expensive method. The inspection is one which, in my opinion, will require great tact, and in this the knowledge of the local practitioner would be invaluable.

I am, Sir, yours faithfully,

GENERAL PRACTITIONER.

Dec. 28th, 1907.

A PERSONAL EXPLANATION.

To the Editor of THE LANCET.

SIR,—Will you permit an old correspondent whose first contribution appeared in your pages more than 50 years ago to make a personal explanation? A few weeks ago, in sorting some papers that had accumulated, I came across a circular or report from the Antivaccination Society. Glancing over it I saw a list of correspondents of the society in foreign parts. To my extreme disgust I found my own name published as the New Zealand (or Auckland) correspondent. My only correspondence with the society during the 34 years I have been in this colony was to answer an application from the secretary, who asked me whether I would allow extracts from a paper on Compulsory Vaccination which I had read here before our branch of the N. Z. Institute to be published by the society. My reply was that they might reprint the whole paper (which was not a long one) if they liked, but that I would not allow extracts to be made. I have never had a reply to this. My object in refusing to allow extracts was that I knew they would pick out certain cases of vaccino-syphilis which I had seen in the days of arm-to-arm vaccination, and not reprint the statement I made that no one who had seen a bad case of confluent small-pox would hesitate about preferring the risks attendant on vaccination to the risks of incurring such a disease as small-pox. But as small-pox has never been epidemic here I see no necessity for enforcing vaccination.

I may mention that as physician of the small-pox hospital in Port of Spain, Trinidad, during the epidemic of 1871–72, I saw two cases of confluent small-pox both of whom had had confluent small-pox before in the severe epidemic. One I had had under my own care, the other one was seen in the hospital by the medical man who had attended him in the first attack. These cases are given in my little work on "The Pathology and Treatment of Small-pox," published in 1872. I have had to bear a good deal of odium on account of my opposition to compulsory vaccination, and some people have treated me as a heretic about vaccination. I am perfectly orthodox on the subject and always have been.

I am, Sir, yours faithfully,

R. H. BAKEWELL, M.D. St. And.,
Surgeon-Captain (retired) Army Medical Staff.

Auckland, N.Z., Nov. 10th, 1907.

THE POWER OF LOCAL AUTHORITIES TO PROVIDE HOSPITALS.

To the Editor of THE LANCET.

SIR,—The answers to the questions put by "J. S." in THE LANCET, of Dec. 21st, 1907, p. 1793, seem to me to be as follows:—

1. The education authorities have power compulsorily to acquire sites for their hospitals, because the provision of these hospital and vacation school sites, &c., is by Section 13 of the Education (Administration Provisions) Act, 1907, included in the powers and duties of a local education authority under Part III. of the Education Act, 1902. For the purposes of Part III. of the Act of 1902 land may be taken in one of three ways: (*a*) by agreement under the agreement sections of the Lands Clauses Consolidation Acts, which Acts are expressly incorporated in the Elementary Education Act, 1870, c. 75, s. 20 (1) (unrepealed); (*b*) under the School Sites Acts (Elementary Education Act, *1870*, c. 75, s. *20*, last clauses unrepealed); (*c*) "Otherwise than by agreement," that is, compulsorily under the Land Clauses Consolidation Acts.

2. With regard to the question of employing qualified medical practitioners I think that the education authority can employ any suitable person, whether a qualified medical practitioner or not. There is no provision in the Act. Section 133 of the Public Health Act, 1875, gives the local authority power in cases *of any formidable* epidemic disease to "appoint and pay such medical or other officers or *persons* and do and provide all such matters and things as may be *necessary for mitigating* such disease, or for superintending or aiding in the execution of *such regulations.*" Although that section only applies in case of a formidable epidemic, yet we may draw the inference that as the local education authority *has authority* to establish hospitals it has the power to appoint any qualified nurses, or, *in fact*, any suitable person to look after them. In the case of a small-pox hospital the *Local* Government Board has not objected to the medical officer of health acting as *medical* superintendent, but it considers, in view of the duties which he has to perform as medical officer of health, that it would be undesirable that he should *reside* in the hospital.

3. I think that the treatment need not be *free, for* the education authority has power under the Elementary Education Act, 1870, c. 75, s. 3 (still *unrepealed*), to charge pupils for education in their elementary *schools* any sum not exceeding ninepence per week per scholar, consequently the authority would *seem to* have the power of charging for medical attendances when the parents are capable of paying.

4. The authority does not appear to have the power to admit to such hospitals the children of ratepayers who do not send their children *to the elementary* schools, for Section 13 specially mentions children attending elementary schools.

5. I think that the local education authority may, with the approval of the Board of Education, supply free of charge spectacles and surgical appliances under s. 13, subs. 1 (*b*) of the Act of 1907. I think that the words, "the power to make such arrangements as may be sanctioned by the Board of Education for attending to the health and physical condition," confer such power.

6. I am of opinion that the authority can decide that the child requires spectacles and that the parent can afford to pay for *them*, and if the child comes to *school* without spectacles the authority can refuse it admission and prosecute the parent for not sending it to school, as such a rule would

been seen alive by them about 5.30 P.M.; half an hour after both were dead, lying on their sides, faces not covered up, some distance apart. Post-mortem examinations showed a similar state of broncho-pneumonia; there were no injuries and no suspicion of foul play.

I am, Sir, yours faithfully,
W. W. WESTCOTT,
Coroner.
Dec. 28th, 1907.

LONDON'S MILK-SUPPLY.

To the Editor of THE LANCET.

SIR,—I notice in THE LANCET of Dec. 21st, 1907, p. 1778, that a reference is made to the adoption of new regulations by the Hailsham rural district council under the Dairies, Cowsheds, and Milkshops Orders 1885, 1886, and 1899. In the same article you imply that the Hailsham council has had no Dairy, Cowshed, and Milkshop Regulations for the past 20 years. You have evidently been misinformed. As a fact the Hailsham rural district council was one of the first councils to make regulations under the Dairies, Cowsheds, and Milkshops Orders 1885, 1886, and the old regulations were more strict than the new regulations. The Hailsham council, acting on the advice of its medical officer of health, has recently brought the above regulations up to date and these remodelled regulations will come into force on Jan. 1st, 1908 It is no doubt these revised regulations that your correspondent has mistaken for the Order. I would point out that the *Dairies, Cowsheds, and Milkshops Order* is not adoptive as described in your article under London's Milk-supply.

I would also draw your attention to the fact that the Order does not compel local authorities to make regulations, but, unfortunately, merely empowers them to do so, and the Legislature should doubtless have made the making regulations under the Order compulsory instead of permissive. It is a matter for deep regret that your usually accurate journal should be blemished by a contribution the author of which shows want of knowledge, both as to his legal principles and facts.

I am, Sir, your obedient servant,
HUGH STOTT,
Medical Officer of Health, East Sussex Combined Sanitary District.
Dec. 26th, 1907.

*** We are sorry to find that our correspondent has made a mistake.—ED. L.

MEDICAL PRACTICE IN TURKEY.

To the Editor of THE LANCET.

SIR,—Perhaps it may interest a few of your readers to know how the licence to practise medicine in the Turkish Empire is to be obtained. Perhaps this licence is not absolutely necessary for an English practitioner whose work lies solely in an English institution, yet it is strongly recommended to be obtained as without it one has no *legal* right to practise.

First from the Consulate (fee 10*s.*), or from some friend who can write a formal Turkish letter, a "petition" is obtained stating that X, a British subject, graduate of such a University, desires the licence of the Ottoman Government. This letter addressed to the Director-General of Medical Affairs (Nāzir Mekteb Tibbiyé Shāhāné) you take to the Haidar Pasha new military medical school near Skutari, to a room called *evraq odasy*. There a clerk gives you a form bearing a *number* (fee 20 paras = 1*d.*), and you are probably told to call in a week's time. Meanwhile, the petition goes before some authority and on your next visit you pay in an adjoining office (*Bureau de Comptabilité*) £T.20 + 20 paras; *no receipt is given yet.* Five days later, probably, on visiting the original office and displaying the number, the clerk, turning up his register, writes "council" on your form, and after waiting an hour or so you enter to see the council which examines your university diploma and *medical registration certificate.* The former it retains, *all things being satisfactory*, and you enter an adjoining room for a *vivâ-voce* examination by the professor of anatomy, of surgery, and of medicine. This examination is a perfectly fair gentlemanly one. If you display a reasonable knowledge of your profession you are immediately afterwards invited to the council-room where the chairman declares your acceptance.

The examination must be taken in French or Turkish. An interpreter is allowable. Then comes a wait of some ten days during which your diploma and the result of the test, &c., pass to the Director-General and are finally returned to the school. It is necessary in the meantime to pay a visit to the Sublime Porte to have your passport legalised (fee half Turkish pound + 2 piastres). The return of your papers is announced in Turkish on a notice board in the hall in which you do so much waiting. Your university diploma is now returned to you and also a receipt for the fee, and after a period varying according to whether there are others ready with you or not, you are led before the Director-General to swear the oath not to procure abortion, not to treat hardly the poor, to call your professional brethren in consultation when necessary, &c., and after paying 21 piastres (3*s.* 6*d.*) for a stamp, your licence is handed to you. The examination and council, &c., are held three times weekly—Mondays, Thursdays, and Saturdays, and it is advisable to call regularly on each of these days when waiting, as the clerk's instruction to come in a week's time is but a way of speaking. In the first office and the fee-paying office there is no one who speaks French. The whole affair takes three weeks if very fortunate, five weeks usually, and seven weeks if unfortunate. In Egypt the same affair takes from four to five days and there is no examination and a nominal fee of 3*s.* 6*d.* or so to pay.

I am, Sir, yours faithfully,
P. A. H. RADCLIFFE, M.B. Vict., D.T.M.
Baghdad.

THE TREATMENT OF PUERPERAL SEPSIS.

To the Editor of THE LANCET.

SIR,—In a letter in THE LANCET of Dec. 21st, 1907, p. 1785, Dr. Amand Routh says, "I cannot recall any acute septic condition of the endometrium where curettage with a sharp curette has done good." I should like to bring forward some statistical evidence on this point. In the *Journal of Obstetrics* for January, 1907, in a paper dealing with the treatment of puerperal sepsis, I wrote: "Out of 79 cases (of my own) treated by general means, with or without intra-uterine douches, 37 died—a mortality of 46 per cent. In 86 cases where the method I have described was employed the mortality was 23 per cent. only." I can now add to the latter series 43 more cases with 11 deaths. The method referred to consists in the removal of the endometrium as completely as possible with a large sharp curette followed by swabbing of the resulting raw surface with undiluted izal.* I should add that all the patients were intensely ill when I first saw them and that the large majority had been treated previously by intra-uterine and vaginal douches for several days, the average day of admission to hospital being, in fact, the fifth of the pyrexial period or, in other words, the stage which is certainly not the most favourable for the use of the sharp curette. I do not see mild or early cases at all.

I am well aware of the fallacies which attend the use of the statistical method in such a complex disease as puerperal sepsis, but I think it is evident that these figures do not justify the inference that the use of the sharp curette is *per se* either dangerous or inadvisable and that the number of cases, 208 in all, is sufficiently great to be worth quoting in this connexion.

I am, Sir, yours faithfully,
A. KNYVETT GORDON.
Monsall Hospital, Newton Heath, Manchester, Dec. 22nd, 1907.

NOTIFICATION OF BIRTHS ACT.

To the Editor of THE LANCET.

SIR,—The town council here has adopted the above Act and I shall be compelled under a penalty to notify all my confinement cases without receiving any compensation therefor, which is not quite just. However, the spirit of the Act is a step in the right direction and one must not complain. It seems a pity that the scope of the Act did not enable the local authorities to take an interest in both the mother and the child at parturition. Obstetricians who have the true spirit of their office must have felt unhappy and uncomfortable after refusing to get out of bed to attend a woman in labour who had been so improvident as not to have engaged anyone to attend her, knowing well from past experience that the only recompense that these improvident people afford is the approving conscience of having done your duty, which is very satisfying at the time, but of no avail in paying the bills of the butcher,

be reasonable. (See the case of a verminous child in THE LANCET, Nov. 9th, 1907, p. 1342.)

I am, Sir, yours faithfully,

Dec. 28th, 1907. A LAWYER.

THE NEEDS OF LONDON MEDICAL STUDENTS.

To the Editor of THE LANCET.

SIR,—In the controversy now proceeding with regard to the allied, but by no means identical, subjects of the title of "Dr." and degrees for London students of medicine it is as well to endeavour not to confuse the real issues. There is, on the one hand, a demand that the degree of "M.D." should be in some way brought within the reach of all those who are of average mental capacity and have studied medicine sufficiently to pass a qualifying examination. There is, on the other hand, the demand that all those who have passed any qualifying examination should be entitled to assume the prefix of "Dr." With regard to the former, what we desire to know is, What are the impediments which prevent all London medical students from matriculating at the University of London? When these are clearly set out it will be easy to consider what modifications can beneficially be made in the existing regulations. The second demand is quite on a different footing. It seems that the public has made up its mind that a university education is of advantage in a doctor and prefers to go to those who have obtained the stamp of "M.D." Those who have not obtained this stamp therefore declare that they are at a disadvantage and that they must be allowed to pretend that they have obtained the coveted stamp by placing the title "Dr." before their names. This appears to be a distinctly dishonest expedient, and the dishonesty is not lessened by the fact that the word "doctor" is the recognised popular term for a medical man. A solicitor does not put on his brass plate "Solicitor J. Jones," but "Mr. J. Jones, Solicitor." There would presumably be no objection to a doctor who was not a member of a university similarly putting "Mr. E. Smith, Doctor." I venture, however, to prophesy that this would not satisfy the claimants for the title "Dr." Yet if it does not, it seems clear that what they desire is not to be known as doctors but to be falsely reputed to have obtained a university degree. While, therefore, there is every reason to endeavour to facilitate the entrance of students of medicine at the London and other universities, there is none for altering the present arrangements by which the M.D. degree is obtainable only by members of a recognised university. Nor does there seem any reason to complain that London has but one university, so long as that university embraces many constituent schools scattered over the metropolitan area, at which there is plenty of room for medical students.

I am, Sir, yours faithfully,

Dec. 29th, 1907. VERAX.

To the Editor of THE LANCET.

SIR,—Year after year one reads in the columns of THE LANCET letters from discontented individuals who wish to get an M.D. degree without working for it. The case is always the same: Mr. Smith, M.R C.S. or L.S.A., is ashamed of his qualifications and jealous of his neighbour Dr. Jones who has gone through a much more advanced course of study and obtained the degree of Doctor of Medicine. The arguments adduced by the advocates of the "M.D. England" and repeated with such monotonous regularity are decidedly amusing and would make interesting reading did not their

One can almost imagine the learned Primate of all England, suitably robed for the occasion, personally conducting a *vivâ voce* examination in medicine with the aid of the most recent edition of the "Family Physician." But seriously, such retrogressive steps as suggested in these two letters would simply be an absurdity to the intelligent, and demoralising by their conscious support of falsehood and fraud.

I am, Sir, yours faithfully,

Kensington, Dec. 24th, 1907. M.D., M.R.C.S., L.R.C.P.

CHOLERA IN RUSSIA, PERSIA, AND TURKEY.

(FROM THE BRITISH DELEGATE ON THE CONSTANTINOPLE BOARD OF HEALTH.)

THE outbreak of cholera in Russia is now subsiding. It has not been a severe one in comparison with many that have occurred there in the past. It has, nevertheless, carried off a not inconsiderable number of victims. The total number of cases officially reported since the beginning of the epidemic on July 3rd down to Nov. 6th[1] is placed at 11,472 and that of deaths at 5493. The official returns for the six weeks preceding the date just named are set forth in the accompanying table. The figures therein contained are in continuation of those published in my preceding letters.[2]

The weekly totals, as given in the last line of the table, are those officially returned by the Russian Government; it will be observed that they are incomplete and do not quite coincide with the sums of the individual figures in their respective columns. It is probable that all the figures must be regarded as approximative only. In European Russia the towns and governments along the valley of the Volga have been among the worst sufferers from the epidemic, but the town of Kief has also been the scene of a serious outbreak. In Asiatic Russia the government of Tomsk and the Akmolinsk territory have been the most severely affected, and it cannot escape remark that nearly all the governments and provinces of Siberia, including the Transbaikal territory, have been invaded by the disease.

The outbreak of cholera on Turkish territory, on the road between Kars and Erzeroum, reported in my last letter, seems to have subsided rapidly. Later information states that there were two groups of Russian emigrants, both from the Caucasian province of Daghestan. The first, of 94 persons, reached the Russo-Turkish frontier post of Kentek on Oct. 22nd and left on the next day; the second arrived there on the 24th and left on the 26th. Most of the cases appear to have occurred in the second group. Only villages on the line of march of these emigrants were affected by the disease.

A death from cholera recently occurred in Constantinople. The deceased man was one of a group of Mongolian pilgrims on their way to the Hedjaz. This group had come from some portion of the Chinese Empire, by way of Tashkent and Odessa. It had taken them 45 days to reach Tashkent; thence they travelled by rail, arriving in Odessa in five days; they stayed a day or two there, took ship to Sinope, where they underwent five days' quarantine and the disinfection of their clothes and effects. It may be added that they sailed from Odessa on Nov. 5th (New Style), reached Sinope on the 7th, left there on the 12th, and arrived in Constantinople on the 13th. It was only in the night of the 14–15th that the symptoms of cholera appeared in one of them; he died 24 hours later. A bacteriological examination was made and a bacillus was isolated possessing almost all the characters of Koch's comma vibrio; the points in which it differed from the latter were that it coagulated milk and did not give the cholera red reaction. The case was treated in all respects as one of cholera; the large *khan* in a densely crowded quarter of Stamboul where it occurred was evacuated, all the other pilgrims of the same group were removed to the lazaret at Kavak, at the northern entrance of the Bosphorus, where they did 15 days' quarantine, the *khan* was disinfected, and other precautions were taken. A second case of illness occurred in the group, but clinically, pathologically, and

---

[1] Where not otherwise stated the dates mentioned in connexion with the epidemic in Russia are all according to the Old Style, both in the text and in the table.

[2] THE LANCET, Oct. 19th (p. 1119) and Nov. 30th 1907 (p. 1671).

bacteriologically it appears not to have been one of cholera. No other cases occurred in Stamboul.

A far more serious outbreak of the disease is now running its course at the lazaret of Sinope, on the southern shores of the Black Sea. The pilgrim steamer, *Gregory Merck*, which had left Odessa on Nov. 22nd (New Style), arrived at Sinope on the 24th with 2100 Moslem pilgrims on board. They were subjected to the five days' quarantine now in force for such ships. Some suspicious deaths seem to have occurred among them at or before their arrival there. On the 28th it was reported that a severe outbreak of cholera existed among the pilgrims from this ship and the daily telegrams received since have confirmed both the intensity of the outbreak and the difficulty in bringing it to an end. Between Nov. 27th and Dec. 1st 54 cases with 36 deaths were reported; on the 2nd there were 2 new cases and 1 death, on the 3rd 5 cases and 6 deaths, on the 4th 4 cases and 5 deaths, and on the 5th 3 cases with 3 deaths. The totals on the 5th had reached the high figures of 68 for the cases and 51 for the deaths. This outbreak proves once more, if proof were needed, the exceptional danger that masses of Moslem pilgrims present for the spread of cholera. It is noteworthy that Odessa, the port they had sailed from, is, so far as is known, a "clean" port—that is to say, no case of cholera is known to have occurred there. The pilgrims in question had, however, evidently come from, or traversed, some of the infected regions enumerated in the accompanying table, and the infecting material there acquired must have remained dormant, either in their persons or in their clothes or effects, until about the time of their arrival at Sinope.

In consequence of this outbreak it has been decided that all ships from Russian ports of the Black Sea will undergo a thorough inspection on arriving at Kavak at the entrance of the Bosphorus; if a case of cholera is found on board the ship will be sent to the Sinope lazaret (if it is in a condition to receive any more ships) or to the Russian lazaret of Theodosia, where the Russian Government has consented to receive them. If no case is found at the inspection the ship, if there are no pilgrims on board, will be quarantined at the Kavak lazaret; but if there are pilgrims on board she will be sent to the Clazomene lazaret, near Smyrna. A number of other measures, which it would take too much space to mention in detail, have also been put in force to diminish the risk of further spread of cholera by pilgrims travelling from Russia by sea or land. The measures on land have been shown to be necessary by the discovery that a number of pilgrims were leaving Russian territory by way of Roumania or Hungary and, striking the main Oriental railway at some point, were arriving in Constantinople by train. In addition to the above measures the Board of Health has formulated a "*vœu*," desiring the Russian Government to do all in its power to prevent the spread of the disease by its pilgrims and adding that the end could best be attained by subjecting those pilgrims to disinfection and isolation for a fixed period before their departure from Russian territory. Under Article 87 of the Paris Sanitary Convention of 1903 this measure is compulsory, if local circumstances permit, if the port where the pilgrims embark is infected. It is not, perhaps, clear whether this article is of general application, or applicable, like Article 86, only to ports of the Indian Ocean and Oceania. It is in any case desirable that the preliminary observation before departure, which has proved to be of such value in India in preventing the spread of plague and cholera from that country, should also be applied to pilgrims leaving Russian Black Sea ports. The outbreak at Sinope has shown what a real danger those pilgrims can be; indeed, owing to the proximity of the ports in question, such pilgrims offer a greater danger for the rest of Europe than those embarking in ports of the Indian Ocean or Oceania.

Some cases of cholera recently occurred in the lazaret of Camaran, in the Red Sea, among pilgrims from two British ships. There were three cases from the first ship and three from the second. In reviewing the records of this great lazaret it is a striking fact that between 1890 (when complete records begin) and 1895 inclusive cholera was imported there on 11 occasions; between 1898 and 1906 inclusive it was not imported on a single occasion; now, in the first two months of the 1907 pilgrim season, it has been twice imported. In 1896, it will be recalled, plague first appeared in Bombay; in 1897 the pilgrimage from India was prohibited; since that date it has been permitted, but under certain precautions, the most important of which have been the individual inspection of the pilgrims before embarking, the disinfection of their clothes and effects, and the isolation of the pilgrims in an observation camp for a fixed period before their departure. Some or all of these measures remained in force until the autumn of 1906, when the isolation before departure was abandoned owing to the fact that the pilgrim season, now and for some years to come, tends to fall more and more in the rainy season when such camps become almost uninhabitable. The fact that the Camaran lazaret (to which all Indian pilgrims are sent before admission to the Hedjaz) remained free from cholera from 1898 to 1906—that is to say, for just that period during which the departure of pilgrims from India was prohibited or only permitted under strict precautions—whereas in the six preceding years importations of cholera there were frequent, and in the early months of the subsequent season two such importations have occurred, shows in a very striking manner the great value of the precautions in question, and justifies the conclusion that among those precautions the isolation of the pilgrims before departure must be regarded as one of the most efficacious. The measures in question, it should be added, were imposed with a view to prevent the spread of plague from India, but they have been equally effective in controlling at the same time the diffusion of cholera.

The reports received here of the behaviour of cholera in Persia are very incomplete and conflicting. Some cases appear to have occurred in the fisheries on the southern shores of the Caspian; on one or more ships plying between Astrakhan and Persian ports; and at Astara, close to the Caucaso-Persian frontier. A deadly epidemic is stated to be decimating the garrison and population of Kuh-Malik-i-Siah, on the frontiers of Persia and Beluchistan, but the nature of the disease is not known. Persia is reported to have closed her Russian land frontiers, except at the four points of Djulfa, Khoudaferin, Astara, and Shahtadé, where passengers are submitted to a medical inspection and other measures.

Constantinople, Dec. 9th, 1907.

THE *LUSITANIA*.

A VAST EXPERIMENT IN VENTILATION.—AN EXAMPLE THAT MAY SERVE ON SHORE AS AT SEA.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

THE *Lusitania* and the *Mauretania* are two floating towns. Big liners have often been compared to floating hotels; but in any case, for these, the two largest ships in the world, the word "town" is more appropriate. Besides, the word "hotel" does not cover all the intricacies of the problems that have to be solved and the difficulties that must be overcome. A hotel may be a first-class or a second-class hotel; there are not different classes of hotels under one and the same roof and management. These big ships, on the contrary, are not only first-class hotels but they are also second-class and third-class hotels and hold besides quite a large professional, artisan, working-class, and labouring population. In a word, all the gradations of people and occupations which constitute the population of a town are to be found on board. There is the fashionable promenade deck, where of late, on the Booth Line as well as on the Cunarders, has been introduced the French café, with its terrace, round tables, and light refreshments served in the open air. Adjoining there are not the small cabins where two or four passengers sleep in such restricted space that only one of them can dress at a time but regal suites of rooms, drawing-room, dining-room, bedrooms, with real beds instead of bunks, and a private bathroom. Yet, while there are public and private saloons and other apartments that equal in luxury and art decorations the most beautiful palatial residences, these floating towns have also their poor industrial districts and even what might almost approximate to their slums. It is the firemen's quarters that generally constitute the slum of a ship. On shore there are two main causes that bring about the existence of slums. There are, on the one hand, the defective construction of the dwellings and the unscrupulousness of the speculators in slum property; and, on the other hand, the disorderly, thriftless, and dirty habits of the dwellers in the seslums. Legislation, at sea as on shore, has stepped in to mitigate these evils. At sea the law used to stipulate for 72 cubic feet of space and this has now been increased to 120 cubic feet. The law not only attempts by such enactments to prevent overcrowding in the quarters occupied by a ship's crew but

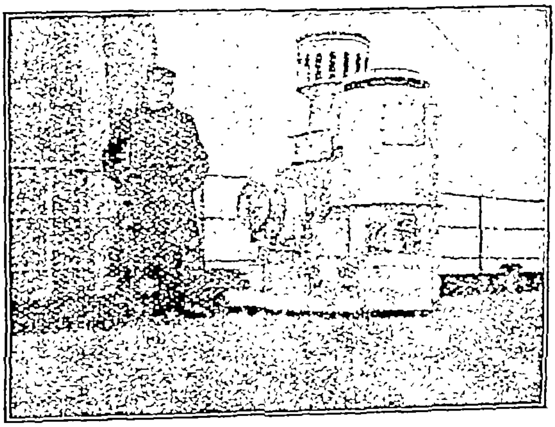
coffee had to be brought down to the landing stage so that the emigrants might be fed and kept warm. Finally the hope of starting that day was abandoned and all the emigrants marched back to their lodgings, and rooms were secured in the hotels for the first- and second-class passengers. By this time I had learnt something as to the difficulties of navigation in such a climate as ours but was not any further enlightened in regard to the problem of ventilation. Fogs of such density as completely to paralyse all traffic on the Mersey do not often occur but they are to be expected occasionally. As, however, they may at any moment and quite suddenly disappear the passengers dare not leave the pier. In such circumstances it seems to me that better shelter and better and more numerous fires might be provided in better furnished and more comfortable waiting rooms. The Prince's landing-stage at Liverpool is a very pleasant and interesting place on a fine summer's day but it is just the reverse during rigorous winter weather.

On the next morning a little after 6 o'clock telephone messages were ringing up the passengers at all the hotels and by 8 o'clock a large crowd had already gathered on the pier. Soon the great ship loomed through the morning haze and was lashed alongside; then with incredible speed all the passengers and all their luggage were taken on board. This haste, however, was of no service; the big ship moved away from the landing stage but could only descend the river a mile or two and then the fog once more thickened and it was necessary to cast anchor. But, in any case, I was at last on board the ship and profited by this delay to have a thorough look round. It was, however, soon obvious that the ventilating system was not yet in working order. The experience acquired on this occasion was very valuable. It conclusively demonstrated that it does not suffice to have a system of ventilation installed, however perfect it may be. Indeed, it seems only natural to conclude that the better the system the greater will be the intelligence required in its handling. It is only technicians who should be intrusted with instruments of precision. It would not be wise to hand over expensive chemical scales to the tender mercies of a greengrocer. Obviously the study of navigation does not include the management of ventilating fans and steam coils used for warming purposes. On the *Lusitania* the officers' quarters really consist of a small separate house built on the upper—that is, the navigation—deck, with its own special thermo-tank on its roof or deck. These thermo-tanks, the manufacturers state, "are capable of changing the air either by exhaust or supply in the various compartments to which they are connected at least ten times per hour and they are also capable of maintaining a temperature of at least 65° F. in the coldest weather." Doubtless this is so when they are properly managed. Fig. 1 is the reproduction of a photograph which I took of the thermo-tank above the officers' quarters. There is, it will be seen, no lack of means to regulate the supply of air and heat. Nearest to the part containing the rotary fan to the left is a valve for regulating this fan when used for exhausting purposes. In that case the mushroom covering of the cylindrical part which contains the steam coils is raised to enable the air drawn from below to escape. If the fan is made to revolve in the contrary direction then it pumps air down after passing it over the steam coils when it is desirable that it should be warmed. The second valve regulates the supply of air; the third regulates the supply of steam to the heating coil; and the fourth regulates the flow of steam from the heating coil back to the condenser. But that is only a part of the mechanism. There are means of regulating the velocity at which the fan revolves when it pumps the air into the ship and so directing the fresh air that only a portion of it goes over the heating coils and the rest descends fresh into the cabins. There is also means of discharging a small atomised steam-jet into the air so as to add moisture in excessively dry weather. With all this at their disposal I had hoped to find the officers living in an ideal atmosphere and temperature. As a matter of fact, the apparatus had been so worked that after suffering from such excessive heat that the woodwork in the cabins showed signs of warping the officers were glad to cut off all connexion with their thermo-tank. Consequently, as there were no other means of warming, the cabins were very cold, and as for ventilation that depended on the accident of open doors or portholes. Of course, this state of affairs will not last. The thermo-tank will have been set to work again and this time it is to be hoped properly regulated. But the incident is instructive, because it shows that even with the best machinery ventilation cannot work automatically: it must be watched and controlled carefully and by a technician.

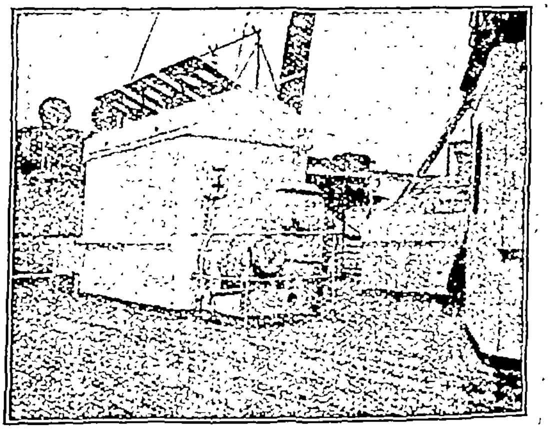
FIG. 1.



The thermo-tank ventilating and warming apparatus for the officers' quarters.

In the firemen's quarters the experience was just the reverse; their thermo-tank was working vigorously, in fact too vigorously, and the air which it sent down was too cold. Consequently most of the air inlets were closed. A fireman was attempting to sleep in an upper bunk within three or four feet of the trunk shaft in which the air descends and which is affixed to the roof of the cabin. There was a valve just facing this fireman and I opened it. Obviously had I not closed it again the man could not have remained in his bunk. The cold air rushed in with great force creating a dangerous draught. Evidently the thermo-tank supplying this compartment was working too fast and had not warmed the air sufficiently, if at all. Then there was no sort of baffle, nothing to break up and to disperse the current of air as it rushed through the valve aperture. But it is not necessary to pump the air down at such a rate that it creates a nuisance. Fig. 2 shows a thermo-tank placed outside a structure which serves as a light and air trunk to the condenser room and stands on one of the decks reserved for the second-class passengers. Above and to the left a small box-like arrangement with two pipes coming out underneath is called the "starting rheostat." This is used for starting and regulating the speed of the fans. Therefore the velocity at which the air travels can be controlled; only someone must watch in order to see what is needed and to act accordingly. Then I photographed a row of thermo-tanks near the great funnels which supply the first-class state-rooms. (See Fig. 3.) Just as the air leaves the thermo-tank and commences its journey to the cabins below a small hole has been cut in the trunk air shaft and a thermometer

FIG. 2.



A thermo-tank for the second-class cabins, showing the "starting rheostat."

an improvement of about £300 on the collections of the previous year. So far as it goes this is satisfactory, but it is not what was hoped for, and it appears from the statement of the Lord Mayor, who presided at the recent meeting of the friends and supporters of the Hospital Sunday Fund, that the active sympathy and help of all religious denominations which it was hoped would be secured on behalf of the collections were not obtained. This is greatly to be regretted, for the one virtue which should be common to all religions is that of charity. Whilst it must be admitted that the Hospital Sunday collections in Birmingham were not what was desired, the case in Dudley is still worse. In the area from which the Guest Hospital, the Dudley Dispensary, and the Dudley Eye Infirmary receive patients are 146 churches and chapels and the average amount which they collect for hospital purposes is £67 per annum. This is scarcely surprising when it is found that at a meeting called to discuss the question, to which the heads of all the religious bodies had been invited, only three ministers and three laymen attended. Clearly there is something wrong in the Dudley religious organisations, and unless some adequate explanation can be put forward the surrounding districts will be inclined to point to Dudley as an example of considerable laxity so far as the Hospital Sunday Fund is concerned.

The Health of Brass Casters.

An inquiry has recently been held in Birmingham at which evidence was produced by the employers who object to some of the draft regulations which the Home Department has proposed with the object of regulating the arrangements in brass-casting works in order that the standard of health of the workers may be improved. So far as the Birmingham trade is concerned it is obvious that in fairness to the workers something must be done, and judging from the statements made by some of the witnesses useful and efficient means of diminishing the dangers of the work by removal or dispersion of the dangerous fumes can be adopted without the incurring of any prohibitive cost and without impairment of the efficiency of the work. Apparently, however, the brass casting in other places is not the same as in Birmingham and an application was made to the Home Office Commissioner that further evidence should be taken in Glasgow, Newcastle, and London before final regulations were decided upon, and to this obviously reasonable proposition the Commissioner agreed. There can be little doubt that a fair solution of the difficulty of dealing with what is an acknowledged evil will eventually be arrived at and that the workers at the trade of brass casting will materially benefit.

Dec. 31st, 1907.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Christmas in Manchester.

FROM Christmas Day, and even from a few days earlier, to the close of the old and the advent of the New Year Manchester is much given up to holiday, and the same is true of Lancashire as a whole. It is sometimes said that this festival season is more generally, or at all events more heartily, kept than in the south; but however that may be, Manchester can claim that "Dr." Byrom, the author of the best and widest-known of all Christmas hymns, "Christians, awake," was one of her townsmen, and that Wainwright, the composer of the tune almost universally sung to it, was from Stockport. Byrom studied medicine at Montpellier and was termed "Dr." by his friends, but he never took his degree. He was an adherent of, or at least favourable to, the cause of the Stuarts, as is pretty evident from the toast to the King which he is said to have proposed. The version known to the writer, for there are said to be some slightly varying, is as follows:—

> God bless the King, God bless the Faith's Defender,
> God bless—no harm in blessing—the Pretender;
> But which Pretender is, and which is King,
> God bless us all, is quite another thing.

The season is marked at the various hospitals by entertainments to please both young and old, and the inmates of the workhouses are not forgotten. Perhaps the Christmas festivity at the Children's Hospital at Pendlebury may be taken as an illustration of what is done to brighten, for the time at least, the pain and weariness from which the patients too often suffer. There are about 160 children there and on Christmas morning each one finds at the corner of the bed a stocking full of odds and ends. Then large Christmas trees are brought into the wards and round them the nurses are very busy. In due time the trees burst out in a display of coloured lights, while more or less bulky parcels are seen hanging from the branches, each one having the name of one of the little patients, all of whom are keenly interested in the proceedings. The routine of the hospital cannot be suspended too long, but for two hours the children were allowed not only to enjoy their new toys but to be made much of by the visitors whose sympathy and kind words must often cheer the sufferers. The patients are all under 14 years of age and receive presents suitable to their years, some of the older girls, for instance, having work-boxes. Carols were also sung by the members of the choir of Holyrood Church, Swinton, who walked in procession through the wards and corridors. There are, of course, differences in the procedures at the various hospitals, but the main object is to add to the enjoyment or to lessen the sufferings of the patients.

A Large Family.

A female claimant at the St. Helens county cou surprised the judge one day lately by saying that she ha plenty to do with the money, as she had 21 children. This i unusual enough, but even this family was smaller than that of a late rector of Eccleston, near Chester, who was sometimes said to have had 21 children twice over, the fact being that after the death of the twenty-first child another was born, so that his wife was the mother of 22 children.

Death of Mr. E. M. Wilkins, M.B. Vict., M.R.C.S. Eng.

Dr. Eric Maurice Wilkins, son of the late Professor Wilkins of the Victoria University, was found dead yesterday at his house in Victoria Park. No details are as yet known. He was 27 years of age and was a remarkably skilful athlete.

Coroner's Busy Day.

The festive season is too often shadowed by tragedy. Nearly 20 sudden deaths were reported the other day and inquests were held in 12 cases and the jury were occupied in viewing bodies (that old custom against which so much can be said and something also in its favour) for almost three hours. Four children sleeping with their parents were found dead in bed. The coroner took a very charitable view of the matter, attributing it in part, at all events, to the very cold weather. In all likelihood the children habitually slept with the parents without fatal accident, but if the indulgence of a little extra drink at Christmas time had been yielded to the probability of overlying would be enormously increased. It is, however, the idea among parents that there is no danger in the practice if we may judge by the answers to the questions put by the coroner. Two women, one aged 60 and the other 58 years, were killed by falling down cellar steps on Christmas Day.

Crowded Asylums.

The overcrowding of the County Asylum is becoming more acutely felt. The Lancashire Asylums Board has intimated to various boards of guardians that it wishes them, if possible, to accommodate some of the harmless chronic patients. The Prestwich guardians have just discussed the subject. It was suggested that when the new union infirmary was opened in the year on which we are just entering some room would be available at Crumpsall. The house committee is to consider the question. It seems as if all estimates tend to grow so vigorous as to be irrepressible. Then, too, the problem of the unemployed, some of whom if they seek for *employment* do not want *work*, and the unemployable is always present, and *apropos* of this the board approved a resolution passed by the parish of Paddington urging on the Local Government Board the necessity of speedy legislation for the establishment of "labour colonies" on the lines of the Swiss system.

The Manchester Crematorium.

The annual meeting in connexion with the Manchester Crematorium was held yesterday. The report states that in the year 104 cremations took place and that there was a profit of £100. The chairman said that the late Bishop Fraser, Bishop Moorhouse, and Dr. Knox, the present Bishop of Manchester, all approved of cremation. The secretary said he thought that the movement was retarded by the conditions of the it also insists on some sort of ventilation. How such ventilation is to be given in a thoroughly efficient manner is a problem that neither the law nor any other authority has satisfactorily solved. Fortunately there is now before us in these two big ships an earnest attempt made to deal practically with the whole question. This endeavour commends itself all the more to public notice inasmuch as whatever is being done is not done merely for the saloon passengers but more especially for the crew and the third-class passengers.

As with some of the dwellers in the slums of our great cities, so with the firemen on board, legislation can hardly force them to be clean; but by insisting on 120 cubic feet per man this means that there shall be room for lavatories and space to wash. The English firemen, and especially those recruited at Liverpool, have the reputation of being the dirtiest men afloat and they are also the hardest drinkers. So we have here the required characteristics for the creation of a slum. On the other hand, this dirty and intemperate rough is just about the hardiest, the most plucky, and the most persistent worker that can be found in any part of the world. It is only with such men in the stokehole that the blue riband of the Atlantic can be won. But from the sanitary point of view they constitute perhaps the most difficult problem that has to be solved. Fortunately, the firemen's dirt is more offensive in appearance than in reality. His dirt mainly consists of coal dust and this has a purifying rather than a corrupting action. Another great difficulty is that after exposure to the scorching furnaces and the heat of the stokehole, the firemen, when lying down to rest in their bunks, are especially sensitive to draughts. Any ventilator admitting cold air at too great a velocity will very promptly be closed. In the firemen's quarters more than in any other part of the ship is it necessary to divise means for introducing a plentiful supply of fresh air without creating a draught. Thus it will be seen that on a great ship as in a town it is with the poor, the careless, and the dirtier sections of the community that the most puzzling administrative difficulties arise.

Certainly magnificent ships like the *Lusitania* and *Mauretania* represent exceptionally prosperous towns, such as fashionable watering-places frequented by very wealthy people and where real poverty and squalor are almost unknown. Thus out of a total possible population of 3250, which both ships can carry, 550 would be first-class and 500 second-class passengers, and they may be taken as representing the upper and middle classes. Then there is room for 1300 third-class passengers and the crew is set down at 800 to 900. How navigation has changed of late years is shown by the fact that while the engineering department employs no less than 390 persons the sailing department only employs 70 officers and seamen. Then there are 350 stewards, a number of stewardesses, 50 cooks, a band, telegraph and telephone and lift attendants, printers, and others, making up a total crew numbering from 800 to 900 persons. The crew represents a population of workers of all ranks from the captain, the surgeon, and the superior officers who belong to the liberal professions down to the coal trimmer or the washers in the scullery who may be taken as belonging to the unskilled labouring class. To house, to feed, and to keep in health such a mixed population, such a variety of classes, to say nothing of the variety of nationalities, constitutes a series of problems which resemble the difficulties that beset the administration of a town rather than the management of a hotel. All these people, differing so greatly one from the other, have all equal need of lodging, food, and cleanliness of person, clothes, and bedding.

In regard to the *food-supply*, the population of these large ships are better off on board than on shore. Cooking done on a large scale is likely to be more clean and much cheaper than done in detail. Also the food is more strictly examined, not merely according to the usual methods, but also by the special Board of Trade inspectors. Therefore it is probable that more unwholesome food would be found in the retail shops of a town than on board ships leaving an English port. In thus comparing these very large ships to a small town the fact will become evident that we have here an attempt at collective administration for an entire community that may set an example capable, at least in some phases, of application to towns that do not float across the Atlantic but are content with remaining affixed to *terra firma*. Speaking now exclusively of the *Lusitania* and the *Mauretania*, two small floating towns with populations comprising all classes and varying from, say, 2300 to 3250, we have provided for all these people one and the same system of ventilation and likewise the same unique system of cleanliness and washing. It is just conceivable that we may find in this a working example of what might be done, if not for an entire town at least for a district, a cluster of dwellings, especially large tenements and blocks, and more particularly for clusters of small workshops where industrial dust and inefficient ventilation play havoc with the working population.

Over and over again when dealing with ventilation, whether of a great building, a theatre, or, for instance, the Paris Sorbonne, or only Dr. T. Glover Lyon's modest and private dining-room where not more than 14 persons can sit at table, the same inevitable conclusion forces itself forward. Obviously no method of ventilation can be satisfactory unless mechanical force is employed, and intelligently employed—that is to say, modified from time to time as the conditions dealt with themselves alter. It is also obvious—and this is admirably demonstrated by Dr. Glover Lyon's experiment [1]—that mechanical force and scientific ventilation could only be obtained by very wealthy persons if provided especially and solely for one individual. In the case in question the installation for ventilating one single small room would cost at least £150. On board the big ships in question, however, ample mechanical ventilation is supplied not merely to the wealthy saloon passengers but also to the steerage or third-class emigrants and to the poorest among the unskilled workers forming part of the crew. All, rich and poor alike, workers and idlers, passengers and crew, have fresh air pumped down to them all day and all night by mechanical power. Doing this on a wholesale scale certainly does not cost anything like £150 per room capable of seating 20 to dinner. It would be of considerable practical use to know what is the cost per head of the mechanical ventilation applied to these ships.

The system as installed on the *Mauretania* has already been described.[2] This was, however, a theoretical description, and since then I have had a brief opportunity of seeing the same system in actual work on board the *Lusitania*. With the courteous permission of the Cunard Company, and accompanied by the ship's surgeon and also by members of the staff of engineers, I visited all parts of the ship while she was on her way from Liverpool to Queenstown. The weather, however, was not propitious. Everything went wrong and the only consolation is that there is no reason why the experiment should not be repeated in more favourable circumstances. At 7.30 P.M. on Saturday, Nov. 30th, the *Lusitania* was to start from the Liverpool landing stage for Queenstown and New York. At midday I was to take the large tender, the *Skirmisher*, meet the chief engineer, Mr. Leonard Peskett, and spend the afternoon with him examining the whole system of ventilation before the ship came alongside the pier to embark the first- and second-class passengers. Mr. Peskett managed to get on a small tender with some workmen. After crawling through the fog for an hour they came upon the *Lusitania* and it was only after bumping up against her sides that they discovered it was the ship for which they were looking. The other tender which I was awaiting was lashed alongside the *Lusitania* and did not venture to leave the ship till some 12 hours later, at about 1 o'clock in the morning when the fog lifted. In vain I waited on the landing stage in the thick of the fog from noon till nearly 4 o'clock in the afternoon. Some 800 emigrants were there also, as they should have gone on board in the morning by tenders. They suffered from cold and damp, then later from hunger. The little buffet on the landing stage was soon stripped of all its provisions. There were other ships, a Booth line steamer for Portugal and the Brazils and an Elder Dempster line steamer, to say nothing of the cross Channel services to Ireland and the Isle of Man with their quota of passengers, all on the look-out for tenders or ships that could not find their way through the fog, and as these people, numbering more than a thousand passengers, waited and waited for hours they got more cold, more damp, and more hungry. The smaller steamers were at anchor near the landing stage and tenders managed to get off to them later in the afternoon. But the huge *Lusitania* was anchored far away near Rock Ferry and in so thick a fog could not be reached by the tenders. Food in carts and great caldrons of hot tea and

---

It is the unanimous opinion of the Faculty that the only solution of the present difficulty lies in maintaining a complete medical school in connexion with the College with classes covering every subject in the curriculum. It points out that it was the absolute necessity of a proper supply of students for the wards of the Royal Infirmary that caused the Royal Infirmary Medical School to be brought into existence by the managers and this also constitutes the reason why the school should continue to exist in its entirety in the future. It is said that as a hospital without students the Royal Infirmary would fail to secure the services of the most eminent physicians and surgeons upon its staff, except in so far as appointments at the Royal Infirmary might be regarded as stepping stones to similar positions at the Western Infirmary. It has been generally admitted that in the interests of the Royal Infirmary it is eminently desirable that its own medical school should be adequately endowed and affiliated to the University of Glasgow, and it was for the accomplishment of this purpose that the affiliation section was introduced into the Universities Act of 1889 at the instance of the managers of the Glasgow Royal Infirmary. In our opinion (says the memorial) affiliation is the only solution of the difficulty. As to the sum necessary to enable the governors to seek affiliation it is for the Universities Committee of the Privy Council to fix this; the University itself has no say in the matter. In this connexion, however, it is pointed out to the governors that prior to the absorption of the Queen Margaret College for Women by the University the University Court passed a resolution in favour of the actual affiliation of that College, the endowments of which amounted to between £40,000 and £50,000 in addition to the buildings. The memorial then goes on to deal with the probability of University students voluntarily attending their later classes at the Royal Infirmary if their earlier classes were taken at the University. The University has no power to compel any of its students to study in the Royal Infirmary wards, and the St. Mungo's Faculty is of opinion that no means short of compulsion would secure such attendance by men who have for three or four years been attached to another teaching centre. Attention is drawn to the fact that the experiment of sending students to other institutions for their earlier studies was actually made by two of the London schools and this experiment resulted in failure.

The Medical Profession and Notification of Births in Glasgow.

A deputation representing the medical profession in Glasgow waited on the health committee of the town council last week to explain the attitude of the profession towards the Notification of Births Act which the corporation has decided to put into operation in the beginning of the year. The medical men of the city already, through a deputation when the omnibus Bill was under consideration last spring, assured the corporation of their entire sympathy with the object of the Bill, namely, the reduction of the infantile mortality amongst the poorer and less informed classes of the community. They are now of opinion, however, that the means by which this object is sought to be attained in the Notification Act, in the form in which it has emerged from Parliament, are clumsy and in certain respects of a highly objectionable character. The deputation urged that to make notification compulsory for the medical man would be contrary to the obligations of the medical oath. It was further pointed out that the cases with which the Act was intended to deal were not for the most part attended by medical men. This fact was illustrated in recent reports by the medical officer to the corporation, in which he showed that in the Cowcaddens district of the city, for instance, in which the infantile mortality is deplorably high, there was no medical man present in 76 per cent. of the births investigated. The medical profession in Glasgow propose in the case of each birth in connexion with which they are called in to place in the hands of the father or other responsible person a simple form of notification with directions for its transmission to the medical officer of health. The deputation concluded by asking the corporation without adopting any resolution on the subject to accept such notification as falling within the scope of the exemption clause of the Act, which provides that no person shall be liable to a penalty if he has reasonable grounds to believe that notice has been duly given by some other person.

Crathie and Braemar Parish Council: Medical Officership.

At the first meeting of the newly elected parish council of Crathie and Braemar held on Dec. 13th, 1907, it was moved, in regard to the appointment of a medical officer—

> That in the opinion of the majority of the council the appointment of the present medical officer was irregular; that three months' notice of dismissal be given and the usual steps taken for the filling of the vacancy.

Objection was made to the motion that it was incompetent, out of order at the meeting, and at the best only based on a matter of opinion. It was also pointed out that at the date of the appointment referred to a copy of the minutes and all particulars connected were forwarded by the clerk to the Local Government Board and that the clerk received confirmation of the appointment. The motion was carried by 6 votes to 2.

Perth Royal Infirmary: Reconstruction Scheme.

The subscriptions towards the reconstruction scheme for Perth Royal Infirmary now total £14,601.

Dec. 31st, 1907.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Lord Kelvin.

VERY great sorrow in Belfast was felt at the announcement of the death of Lord Kelvin who was born in Belfast in a house still existing in College-square East (No. 18), at present occupied by a member of the medical profession. Lord Kelvin's father, Dr. James Thomson, came originally from Ballynahinch, in county Down, and was professor of mathematics in the old Belfast Academical Institution. He wrote a famous book, "Thomson's Arithmetic," long popular in Ulster, and he was afterwards professor of mathematics in the University of Glasgow where Lord Kelvin studied before going to Cambridge.

The Tuberculosis Exhibition.

On Dec. 17th, 1907, in the presence of a large audience, Her Excellency the Countess of Aberdeen opened the Tuberculosis Exhibition in Lurgan and formed the Lurgan and District Branch of the Women's National Health Association of Ireland. On the 18th Sir John Byers gave a lecture on Why Tuberculosis is so Common in Ireland; on the 19th Dr. John McCaw lectured on Tuberculosis in Children; on the 20th Professor W. St. Clair Symmers gave an address on the Germ of Tuberculosis and some of its Effects; and on the 21st Professor Mettam, F.R.C.V.S., lectured on Tuberculosis in Animals. There were immense audiences and the great success of the tuberculosis exhibition in Lurgan is due to the unceasing exertions of Dr. Samuel Agnew, medical officer of health of Lurgan.

Hospital Medical Reports.

It is always pleasant to record the publication of medical reports by hospitals, for they save much valuable material from oblivion. The latest hospital to publish its records is the Ulster Hospital for Children and Women and Dr. H. H. B. Cunningham is acting as editor. The first issue contains an article by the same gentleman on Adenoids; one on Hæmaturia due to Cystic Kidney, by Mr. A. B. Mitchell; one on Cancer of the Uterine Cervix by Dr. Marion B. Andrews; one on Congenital Lymphangeioma by Mr. Howard Stevenson; and the report of a fatal case of Cerebro-spinal Meningitis complicated by Parturition. We wish these records a successful and long-continued future.

Dec. 31st, 1907.

BUDAPEST.

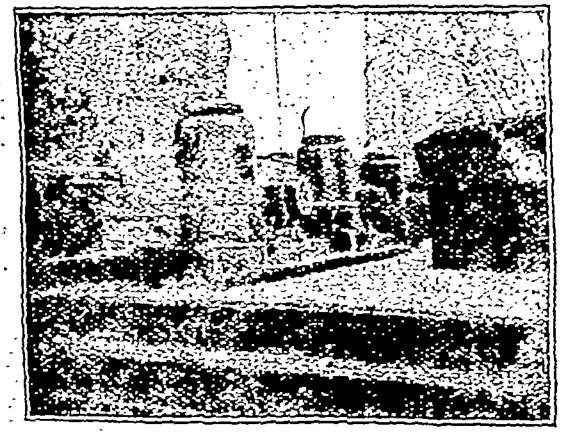
(FROM OUR OWN CORRESPONDENT.)

The Differential Tuberculin Reactions.

AT a recent meeting of the Budapest Royal Society of Medicine Dr. László Detre, *privat-docent* at the University of Budapest, delivered an address on the Differential Tuberculin Reactions. He said that these reactions were of assistance in various ways in the investigation of the biology of tuberculous infection. The researches which he had carried on aimed at the elucidation of the etiology of tuberculosis and the discrimination of a fresh case from an old one. Of late years two questions have received much attention from pathologists—namely, (1) Has the bacillus of bovine introduced. There is a thermometer thus attached to every thermo-tank and it is therefore easy to ascertain promptly what is the heat of the air pumped down into the ship. But again someone must see to this and find out what the heat ought to be according to the distance to which the air has to travel, the needs of the part of the ship which it has to supply, and the general condition of the weather at the time in question.

To meet these ever-varying conditions numerous and very careful experiments will have to be made. Every thermo-tank bears an inscription stating what part of the ship it supplies, and considering the variety of the distance and the disposition of the different compartments no one rule would apply. On the *Mauretania* there are 65 thermo-tanks and they pump air through 17,000 feet of trunking. Thus there are in all three and a quarter miles of air channels, made for the most part of galvanised sheet iron and including some 5000 bends, T-pieces, &c. Is it conceivable that air can be automatically propelled along this enormous distance at exactly the rate and temperature desired? All honour to the constructors of these splendid ships for having introduced such a vast and comprehensive system of warming and ventilating. But it would be a fatal illusion to imagine that all this will work when once wound up like an eight-day clock and that it need not be touched again till the end of the week.

FIG. 3.



A row of thermo-tanks supplying air to the first-class state-rooms.

The *Lusitania* has not quite as many thermo-tanks as the *Mauretania* but there is no practical difference between the two ships. When I looked at the thermometers attached to the thermo-tanks I found that their temperature varied from 55° to 120° F.; this showed that some of these apparatus had not yet been regulated. Doubtless all this was rectified when the ship got further under way. But the fact that this was not done at starting shows how difficult is the problem and how much still remains to be achieved before experience has taught the lessons that have yet to be learnt. It will be necessary to secure the services of a few thoroughly competent engineers to regulate these apparatus, to visit and to watch over all parts of the ship, and to be constantly verifying whether the system is working properly. It will also be necessary in many instances to make considerable alterations in the valves, notably in the firemen's quarters, where the air is admitted, so that it may be split up, diffused, and not create an injurious draught. But it will at once be seen that these finishing touches to the system represent a mere trifling outlay when compared with the vast sums that must have been spent over the thermo-tanks, the 2000 h.p. of electricity used, among other purposes, for setting the fans in motion, the three and a quarter miles of air trunks, the condenser and steam-heating coils, &c. We have now reached the stage when it is only necessary to apply the old saying, namely, "Not to spoil the ship for the sake of a pennyworth of tar." There can be little doubt that in the course of a few months when the necessary experience is acquired the great problem of warming and ventilation will practically be solved in regard to these great ships. Indeed, I have just been informed that the patentee of the ventilation apparatus and the draughtsman who had charge of this particular section of the work sailed in the *Mauretania* on her last voyage to regulate the valves and to see to all the details. As a result no complaints have been made. On Saturday, Dec. 28th, the manager of the ventilating system and the draughtsman sailed with the *Lusitania* and it is anticipated that they will be equally successful in putting everything in order. The whole system has been carefully gone over and there is no reason why the defects should not be remedied now that efficient technicians are on board. If so we shall have here a most valuable object-lesson. Throughout I have compared the ships to towns, and I believe that much of what is done on board could with equal economy and benefit be applied on shore. Why not consider a thoroughfare of large houses, such as Victoria-street, to represent on one side the *Mauretania* and on the other side the *Lusitania*, and proceed to warm and to ventilate all the rooms in a similar manner? The experience now in the course of acquisition on board these great liners may be of use on shore as well as at sea. The entire nation has manifested enthusiastic pride in these magnificent record-breaking ships. For my part I see their utility not merely in regard to quick and luxurious travelling but as a vast field of experimentation where some of the most difficult problems affecting the sanitation of dwellings and of workshops may find an effective and economic solution.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Tuberculous Milk.

THE medical officer of health, Dr. J. Robertson, reports that after prolonged investigation it is found that 14 per cent. of the milk sent into Birmingham contains living tubercle germs. The health committee, having considered the report, has decided to recommend that, in the event of the Government not taking the matter up and as the existing legal powers are not sufficient to enable effective steps to be taken to deal with this "grave danger to the public health," additional local powers shall be sought. The position of the health committee would be strengthened if it could give some definite idea of the effect produced by the contaminated milk in any particular cases.

The Medical Students' Dinner.

The annual dinner of the Birmingham University Medical School was a more than usually successful event. There was a good attendance to meet Dr. W. Hale White and Dr. William Wright, the latter of whom was a great favourite with the students when he held the post of senior demonstrator in the anatomy department at Birmingham. The speeches were good but rather long, and the humorous vein was a little lacking except in Mr. H. G. Barling's reply for the medical school. One opinion that Mr. Barling expressed when he passed into a serious phase is well worthy the attention of the public and of the authorities of schools who are constantly struggling to increase the number of their students. He stated that he would prefer 100 well-educated medical men to 200 who were imperfectly educated, and he expressed the belief that the public would be better served by the former than by the latter.

Distribution of Prizes at the Dental Hospital.

Considering the great demand there is in the Midland district for dentists, it is somewhat surprising to learn from the statements of the speakers at the annual distribution of prizes at the Dental Hospital and at the annual dinner of the Dental Students' Society that the number of the students at the Dental Hospital does not exceed 30. The only reason that can be assigned is that in years gone by the Dental Hospital did not offer all the facilities which could be desired. Such, however, is not the case to-day; the hospital is now one of the most efficiently equipped in the country and the staff are energetic and determined. It may be hoped, therefore, that the number of the students will rapidly increase and that the wants of the district will be properly supplied. Mr. W. F. Haslam, who spoke after the distribution of the prizes, drew special attention to the necessity of students avoiding desultory reading, and his remarks are particularly important to Birmingham students who have a tendency to distribute their energies over too many objects at one time.

Hospital Sunday Collections.

At last the full accounts of the Hospital Sunday collections in Birmingham for 1907 are to hand and they show however, there were no appreciable differences between the two reactions; in these cases Dr. Detre assumed that the infection was "mediated" by both bacilli. He did not consider that one bacillus was the infecting agent and that the other only accompanied it; he held this opinion because there were cases in which besides the great sensitiveness against one species there was no sensitiveness at all against the other. The infection might take place in the following manner—a view which is also taken by Professor Behring. During infancy a child became infected with the bovine bacillus through taking milk, butter, &c., and this bovine infection, if it was not entirely recovered from, created a predisposition to the human infection contracted at a subsequent period by inhalation when sensitiveness against both species developed in the doubly infected diseased organism.

(FROM OUR OWN CORRESPONDENT.)

Malaria.

IT is reported that malarial fever is raging at Smyrna and Konieh. The epidemic is attributed to the many swamps and marshes which are to be found almost everywhere in the above localities. From Konieh comes an urgent demand for a medical man, but the authorities of the medical school in Constantinople think that medical skill will be of very little use if the source of the epidemic—namely, the marshes—is not removed. The municipal authorities of Konieh have, however, been informed that a medical man will be sent to the affected districts. In connexion with this subject the Turkish newspaper *Sabah* publishes some details concerning the irrigation of the plain of Konieh and the drying up of its marshy places which are of medical interest. The schemes proposed for carrying out the work have been approved by the Council of Ministers and sanctioned by the Sultan. Large areas of land will be rendered capable of cultivation and the Anatolian railway, which is now carried as far as Boulgourlou, will shortly reach Adana, the line everywhere traversing fertile land. The water required for irrigation is to be supplied by Lake Beyshehir, situate about 100 kilometres to the west of Konieh. Two small streams, the Beyshehir Sou and Tcharshembe Sou, which provide an escape for the overflow of the lake, are to be canalised and controlled for a distance of about 145 kilometres. A canal of 30 kilometres will be built round the marshy depression at Karaviran, known as the Sogla Gol, and another canal of 20 kilometres will connect the two above-mentioned streams in the narrow Valikova Pass. Several *barrages* and three large reservoirs will also be necessary, as well as an aqueduct and innumerable small canals for the distribution of water for irrigation purposes. It is estimated that it will be possible to supply 600,000 "deunums" with water; in other words, 132,500 acres of land will, it is hoped, now be brought under cultivation. Through this scheme it is expected that not only will the irrigated places produce annually grain of excellent quality sufficient to load at least 20,000 railway wagons but also that in consequence of the drying up of the marshes they will cease to be a source of malaria.

The Italian Hospital.

A service of gratuitous consultation and surgical treatment has been opened in the above hospital by its newly appointed surgeon, Dr. A. de Fabii, who has just arrived from Italy. He was surgeon to the principal hospitals of Rome and it is expected that he will be able to do much good work in the Turkish metropolis. The gratuitous operations will be performed daily from 9 to 11 A.M., excepting Mondays and Thursdays.

Cases of Extraordinary Longevity.

The Stamboul newspapers assert that no other country produces so many cases of extraordinary longevity as does the Ottoman Empire. Not all the cases brought before the attention of the public are genuine or credible, but, on the other hand, an individual is occasionally found whose remarkably great age is proved by substantial testimony. The following case seems to be genuine. At Yeni Baghtché, Stamboul, there resides a certain Hadji Raif Effendi who is 124 years old and who has been the bookbinder of the Military School of Pancaldi for the past 80 years. This man's father died at the age of 142 years. He was named Edhem Pasha and was a Government official. It seems that in Russia centenarians are also found. It is reported (this time it is the *Levant Herald* that is responsible for the news) from Revel in the Baltic Provinces that an Esthonian lady, born in 1783, and therefore aged 124 years, has just thought it about time to make her will in case "anything should happen." The old lady, who was born in the reign of Catherine II., has thus lived in the reigns of seven of the eight Tsars belonging to the house of Romanof-Holstein whose sway dates from 1762.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

Winnipeg General Hospital.

THE city council of Winnipeg has decided to grant the request of the board of governors of the Winnipeg General Hospital to raise the annual grant from $30,000 to $40,000. The former grant had been fixed on the basis of the work done in 1904, but since that time the number of city patients has increased 40 per cent. Last year the hospital undertook several absolutely necessary improvements and additions caused by the great increase in its work. This involved an expenditure of $150,000 and so far the city has paid $125,000 of this amount. For the first time in the history of the hospital it was unable to pay its monthly accounts in October. These amount to about $13,000 per month. The board of governors also asked that the hospital be granted by the city $25,000 at once on debenture account to close out the accounts incurred by building operations last year. They also asked that legislation be obtained to provide for the immediate erection of a proper mortuary and a place for holding inquests, post-mortem examinations, &c.; also a proper pathological department. Winnipeg requires a new isolation hospital; and the board requested that it be erected and conducted by the city and so relieve the General Hospital of the work of taking care of cases of infectious diseases. The cost of such a hospital for Winnipeg is placed at $150,000. It should accommodate from 80 to 100 patients and have provision for from 40 to 50 tuberculous patients.

Toronto Hospital for Incurables.

The annual meeting of the board of management and patrons of the Toronto Hospital for Incurables, formerly called the Toronto Home for Incurables, took place recently. Dr. Bruce Smith, the Ontario Government inspector of such institutions, was present and said that of all similar institutions both in Canada and in the neighbouring country of the United States which he had visited none could surpass the state of this hospital. He also pointed out that the grant of the Ontario Government of $5323 and that of the city of Toronto of $4000 were totally inadequate when the importance of the work was considered. The secretary presented the annual report and showed that during the past hospital year 176 persons had been cared for. On Oct. 1st, 1906, patients numbering 139 were registered, and to that number 37 were added during the year. The deaths in the same period totalled 31; four patients left and there were now in the institution 141. There are 80 patients supported at present absolutely free of cost; 18 pay a nominal amount for maintenance. The present year's work was carried on with the small deficit of $486. The average cost of each patient was 56 cents per day.

Alexandra and St. Paul's Hospitals, Montreal.

These two hospitals in the city of Montreal look after respectively the cases of infectious and contagious diseases occurring amongst the English- and French-speaking population of that city. The first arrangement for the maintenance of these made with the city called for a grant to each of $15,000 per annum, but it has been found that almost a doubled grant would just about be adequate to continue their work. A new agreement is now required from the city council. It is asked that each be granted $5000 for the balance of the present year and that on Jan. 1st next the total grant to each be $25,000, this agreement to last for a term of three years. The hospitals then agree to treat all patients without regard to religious denomination who may be sent to them by the city in such numbers as the said hospitals can accommodate, each accommodation not to be introduced. There is a thermometer thus attached to every thermo-tank and it is therefore easy to ascertain promptly what is the heat of the air pumped down into the ship. But again someone must see to this and find out what the heat ought to be according to the distance to which the air has to travel, the needs of the part of the ship which it has to supply, and the general condition of the weather at the time in question.

To meet these ever-varying conditions numerous and very careful experiments will have to be made. Every thermo-tank bears an inscription stating what part of the ship it supplies, and considering the variety of the distance and the disposition of the different compartments no one rule would apply. On the *Mauretania* there are 65 thermo-tanks and they pump air through 17,000 feet of trunking. Thus there are in all three and a quarter miles of air channels, made for the most part of galvanised sheet iron and including some 5000 bends, T-pieces, &c. Is it conceivable that air can be automatically propelled along this enormous distance at exactly the rate and temperature desired? All honour to the constructors of these splendid ships for having introduced such a vast and comprehensive system of warming and ventilating. But it would be a fatal illusion to imagine that all this will work when once wound up like an eight-day clock and that it need not be touched again till the end of the week.

(FROM OUR OWN CORRESPONDENT.)

Liverpool Education Committee: Medical Inspection of School Children.

THE chairman of the education committee of the city council at its meeting on Dec. 23rd last moved the adoption of the report of the special medical inspection of school children subcommittee, which had expressed the opinion that the work of inspection could best be carried out under the immediate control of the education committee, and recommended that a special medical officer should be appointed for the purpose at a salary of £400 per annum. The subcommittee's intention was to take the medical officer of health into consultation but to retain the control itself. It did not wish to clash with any other corporation committee and according to the chairman of the education committee they had no desire to override the work which Dr. E. W. Hope had already done outside the schools and they desired that that work should still be continued. Alderman Salvidge opposed the recommendation on the ground that it would create a new department, whereas it had not yet been proved that the present health authority was unable to carry out the extra duties suggested. He moved that the recommendation should be referred back to the subcommittee in order that an opportunity might be afforded it of discussing the matter with the health committee. The amendment having been duly seconded was agreed to.

Liverpool School of Tropical Medicine: The Prevention of Yellow Fever.

A despatch has been received by the secretary of the Liverpool School of Tropical Medicine from the Foreign Office respecting the presentation of the Mary Kingsley medals conferred by the school upon Senator Professor Golgi (Italy), Dr. Charles Finlay (Cuba), Professor Danielewsky (Russia), and Professor Theobald Smith (United States). The despatch was accompanied by a translation of a lengthy report from the *Official Gazette* of the Republic of Cuba of the ceremony at which the medal was handed to Dr. Finlay, the discoverer of the mosquito theory of yellow fever, by the Provisional Governor of Cuba. The ceremony took place at the great hall of the University of Havana in the presence of a distinguished gathering, and the speeches delivered were so interesting that some are worth reproducing at some length. The Hon. Charles E. Magoon, Provisional Governor of Cuba, presided, and in handing the medal to Dr. Finlay, said: "An important foreign scientific institution, the Liverpool School of Tropical Medicine, in recognition of the eminent services rendered by Dr. Charles Finlay in his devotion to the cause of science, which culminated in his discovery of the agent by which the yellow fever germ is transmitted, has conferred upon him the Mary Kingsley memorial medal. This medal was designed upon the death of the famous African traveller, whose name it bears, in commemoration of her labours in the tropics, to be bestowed upon those persons who may have distinguished themselves in special work and researches in tropical medicine, and has been received by the Government of Cuba from the Minister of His Britannic Majesty with the request that it be officially handed to Dr. Finlay." The Rector of the University having addressed Dr. Finlay, the latter replied thanking the speakers, the University, and the Liverpool School of Tropical Medicine. Referring to the Liverpool school he said: "I wish more especially to return thanks to the Liverpool School of Tropical Medicine for the honour they have done me in conferring upon me the Mary Kingsley memorial medal. The honour is shared with Colonel W. C. Gorgas of the United States Army. The same distinction has also been bestowed upon Manson, Laveran, Ross, Koch, and others who in different parts of the world are associated with the labours of the school founded by the mercantile community on the banks of the Mersey."

(FROM OUR OWN CORRESPONDENTS.)

Housing in Swansea.

THE Swansea corporation has decided, upon the recommendation of the housing committee, to erect 55 houses at a cost of £160 each, to be let at a rental of 5*s.* 6*d.* weekly, and 44 double tenement houses at a cost of £300 each, to be let at a rental for each tenement of 4*s.* 6*d.* weekly. Arrangements are in progress for holding an exhibition of cottages and a conference on the housing question in Swansea under the auspices of the National Housing Council. The corporation is the owner of several large plots of land in the town and it is probable that one or more of these may be utilised for the purposes of the exhibition.

An Asylum for Swansea.

Since the establishment of the county asylum at Bridgend that institution has been available for patients resident in Swansea. The rapid growth of the county of Glamorgan led the asylum committee to give notice first of all to the Cardiff corporation and later to the corporation of Swansea to terminate the then existing arrangements and to provide separate accommodation for the needs of the two towns. Unsuccessful efforts have been made to make arrangements for sending Swansea patients to the asylum at Talgarth, which is owned jointly by the county councils of Brecon and Radnor, and it appears now to be probable that suitable accommodation will be provided by the erection of a building in the borough of Swansea upon land already in the possession of the corporation. Merthyr Tydvil having become incorporated will also have to sever its connexion with the county asylum and a suggestion has been made that the corporations of Merthyr and Swansea might advantageously combine for asylum purposes. There are over 300 Swansea lunatics at Bridgend and about 200 from Merthyr.

The Cardiff Mental Hospital.

It is expected that the Cardiff Asylum, or, as it is officially designated, the Mental Hospital, will be ready for occupation in about three months' time. The equipment of the institution is very complete and has been carefully thought out—so carefully, indeed, that the committee of the corporation concerned with the erection of the buildings has had to stand a great deal of adverse criticism on account of the cost which has been incurred. This criticism has hitherto had but little effect in preventing the accomplishment of what was really necessary. With such an excellent record it is difficult to understand the attitude of those members of the committee who have been able successfully to postpone the erection of an isolation hospital. In the original scheme this building was provided for at an estimated cost of about £3000, and although the medical superintendent (Dr. E. Goodall) expressed the opinion that the cost need not exceed £2000 it has been decided by 4 votes to 3 to postpone the erection of this building until a future date, presumably until an outbreak of some infectious disease has occurred which will prove its necessity. The majority of the members of the committee were evidently influenced in their decision by a report presented to them showing that although most of the asylums in this country were provided with isolation hospitals they were very rarely used. In spite of this it is quite certain that the Commissioners in Lunacy will quickly draw the attention of the committee to the absence of this very necessary accessory to every well-ordered asylum.

Dec. 31st, 1907.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

St. Mungo's College.

THE Faculty of Medicine of St. Mungo's College has presented a memorial to the governors of the College in which it states its views as to what should be done in order to insure the prosperity and even the existence of the College.

statistics show in his opinion that of the 1,800,000 milch cows in this State 440,000 are infected with tuberculosis. The disease is constantly spreading through the traffic in cattle. The remedy is thorough inspection by a competent corps of State inspectors.

Dec. 19th, 1907.

NOTES FROM INDIA.

(From our Special Correspondent.)

Sanitary Reform in India.

The great event of the past week has been the issue by the Government of India to the various local governments of a letter on the improvement of the sanitary services in India. It is contemplated to employ a greatly increased number of medical officers of health as well as of sanitary inspectors, and more sanitary boards will also be created. There is not a word, however, regarding legislative powers which are at present very deficient, or as to how the expenses of sanitary improvements have to be met. Money is wanted badly by every municipality for public sanitary schemes but the difficulty in effecting improvements is still greater in the case of private individuals. It is hardly recognised sufficiently that the sanitary evils chiefly pertain to the home, and to enforce measures of sanitary improvements in the case of private individuals is often a very serious hardship and perhaps as often an impossibility. The great mass of the people are poor and their unhealthy surroundings are largely due to their poverty. That more executive officers are required no one will question, and it is satisfactory to learn that the tenure of their appointments will be safeguarded by the local governments and will not be subject to the whims and fancies of municipal boards. A very large field of work will be thrown open to Indian medical men who have been trained in England and have taken a degree in sanitary science. This is as it should be, but this concession to Indians must not be carried too far and the higher posts should be reserved for British sanitarians. A temporary medical education in England does not produce that independence and force of character which belong to those Englishmen who have had a life's training at home, and the ingrained habits of life in an Indian tend to reassert themselves when he returns to his native country. It is curiously asserted that though certain appointments will be open to European and Indian officers, on grounds of economy preference would naturally be given to Indian candidates. The principle of prohibiting private practice for health officers is definitely laid down and the pay of such officers will be determined accordingly. A great deficiency at present exists in properly trained sanitary inspectors but an arrangement is contemplated for instituting some form of an examining board. This letter of the Government marks the commencement of sanitary reform but it all depends upon the local governments as to how the proposed scheme will be carried out.

A New Parsi Hospital in Bombay.

The foundation-stone of a large general hospital for Parsis has just been laid in Bombay. It is hardly a generation ago that Parsis refused to go to hospital owing to the joint family system prevailing. First, however, a maternity hospital was started and proved very successful, then a fever hospital was established, which was also successful, and now by the liberality of certain wealthy members of this community, more especially the Petit family, a magnificent hospital costing nearly 14 lakhs of rupees has just been commenced. It will have a magnificent aspect over the sea to the west and will consist of three main blocks connected by corridors. The outer blocks will each contain 120 beds and the central one will include the operating theatre, the laboratory, and rooms for electrical and light treatment. The equipment of the hospital generally will be on the most up-to-date lines. In the operating theatre the students will be shut off from the actual place of operations by plate glass and the sole ventilation of the theatre will be through an antiseptic pump. Considering that the population of the Parsi community in Bombay city is only about 80,000 it must be admitted that they are making most admirable provision for their sick.

Fever in Bengal.

It will be remembered that the prevalence of malaria in Bengal was the cause of a special committee being appointed last year and it has now presented its report. It cannot be said, however, that there is much prospect of success. In addition to the waterlogged condition of the country the main causes of fever are accredited to the insanitary state of the village sites. Any improvement in the latter direction depends largely upon educating the villagers, which is bound to be a very slow process. The report says that the value of sanitation, the prophylaxis of malaria by the use of quinine and mosquito curtains, and the efficient treatment of malaria by quinine are matters which might well be taught in the schools. This is not very promising and the use of mosquito curtains for the poor villagers may be said to be impracticable. The distribution of quinine may easily be effected, but the destruction of mosquitoes in such low country, with water nearly everywhere, is hopeless. A certain amount of improvement may be attained in a few places by suitable drainage but the nature of the country puts many limitations on this procedure. It is natural that the committee should lay stress on the necessity for further inquiry. The medical aspect of the question is to be taken up more in detail.

Dec. 12th, 1907.

AUSTRALIA.

(From our own Correspondent.)

Patent Medicines in Australia.

Under the existing Commonwealth law relating to the admission of patent medicines where a trade secret is involved no regulations can be framed prescribing the trade description unless the Governor-General considers such necessary for the welfare of the public. A new Bill has been introduced in which power is given to make a general regulation requiring a trade description, including disclosure of ingredients, for all medicines or food for infants or invalids, but in individual cases if the Governor-General is satisfied that it would mean disclosure of trade secrets and is not necessary for the public welfare he may allow a modified description. The trade description may require in the case of medicines a statement of the diseases or ailments which they are intended to cure. The practical meaning is that importers must show that a trade secret will be disclosed in order to obtain exemption from stating on bottle or packet its component parts.

Melbourne Hospital Election.

The annual report to the council of the dean of the faculty of medicine in the University of Melbourne contained a paragraph referring to the method of appointing the staff at the Melbourne Hospital. The report suggested that a communication should be made to the hospital managers pointing out that the University entrusts the whole general clinical training of its medical students to the hospital staff. "The present system," the report continued, "of electing the staff is a disgrace to the hospital, to the medical profession, and to the community, and presents a bad example to the medical students. The Melbourne Hospital stands almost alone in its methods of election." The council thereupon directed that the paragraph concerning the hospital should be forwarded to the President of the institution with the strong endorsement of the council and a request to bring it before the hospital committee. When brought before the committee at its last meeting the report met with a very chilly reception. Several members took exception to the strong terms in which it was worded and appeared to regard it as a slight upon their conduct of the institution. On the other hand, the Rev. Dr. Marshall, a member of the committee, expressed the view that the language was perfectly justified. It is probable that reform in some lines will shortly be brought about but in view of the fact that the Government is bringing down a Charities Bill in which some proposals are embodied for the appointment of hospital staffs throughout the state nothing will be attempted until these provisions are open for discussion.

Hospital Saturday and Sunday Collections in Melbourne.

The annual Hospital Saturday and Sunday collections in Melbourne have been very successful. The total amounted to £6884, which is the largest sum received since 1888. Last tuberculosis any power of producing human tuberculosis? and (2) Is it possible to distinguish the bovine bacillus from the human one so as to recognise which infection is present in a given case? The dualistic theory originated with Professor Robert Koch who asserted that bovine tuberculosis and human tuberculosis were quite distinct from one another. There was now positive evidence that these two infections were caused by two kinds of bacillus which although standing very near to each other could nevertheless be distinguished by certain signs. It was to the investigations of English and German physicians that the knowledge of these facts was chiefly due. The statement of Spengler that the two kinds of bacilli could be distinguished under the microscope when stained in a certain manner was not yet verified. A constant difference could be shown in the alkalinity of the bouillon culture of the two bacilli (Smith). An important difference between them was that the bacillus of bovine tuberculosis was much more virulent for mammalian animals than the human bacillus was. One milligramme of a culture of the bovine bacillus injected into a vein of a tame hare killed it within about three weeks, while several months were required for a culture of the human bacillus to kill a similar hare. By means of these differences it was possible to decide whether a given case of tuberculous infection in the human subject was caused by one or the other or by both types.

Up to the present time there were 20 cases known in which the bacilli were of the bovine type. In these cases the cultures were mostly obtained from the mesentery of children suffering from abdominal infection. Bovine bacilli had also been found in one or two cases of tuberculous meningitis and consumption. The difference between the two bacilli was so marked that Weber succeeded in cultivating both bacilli in one and the same case. No method has yet been discovered by which it would be possible to determine the type of bacilli present in a living subject. Dr. Detre has therefore endeavoured to draw some inference as to the nature of the infection from *differences in the sensitiveness* of the infected organism against the poisons of the two bacilli. It was known that tuberculous animals reacted strongly to the poison of the *tuberculosis bacillus* and *that they* reacted in a less degree to the poison of bacilli resembling the tuberculosis bacillus, though differing from it by their acid-resisting property. *The reaction* manifested itself partly in local and partly in general thermal and organic changes. It might, therefore, be assumed that the *organism* was most sensitive *against* the poison of the bacillus which had caused the *infection.* On the ground of this assumption Dr. Detre has compared the sensitiveness *of some persons against the* two kinds of tuberculous poison. In these observations he used the filtrate *from bouillon* cultures of the two bacilli—i.e., the human and the bovine bacilli. *He did not use* tuberculin, because Koch's tuberculin did not contain all the poisons of the bacilli.

Tuberculin and the filtrate *were not* chemically identical and there were also some striking physiological *differences* between them. In early cases of tuberculosis Dr. Detre *has found that* there was an intense sensitiveness against the filtrate; and he *has* observed *individuals* who reacted to the $\frac{1}{1000000}$th of a centigramme of the filtrate, *the symptoms* being strongly marked local œdema and a rise of temperature amounting to 0·3° or 0 4° C. On the other hand, it was known that with Koch's tuberculin such small quantities *never* produced such a reaction. He therefore inferred that the filtrate contained an unstable, easily *decomposing* poison, which might serve to distinguish the two kinds of *infection. His* procedure consisted in giving to tuberculous patients subcutaneous injections of the filtrates from cultures of human and bovine bacilli in the same degree of *dilution. He then* observed which substance and in what concentration produced local reaction. When he injected in one arm of the patient the filtrate of the human bacilli and in the other arm the filtrate of the bovine bacilli considerable hypersensitiveness against the human filtrate could be seen. The *differences* between the effects of the two injections *were* sometimes very striking. For instance, on one side a given dilution, say 1 in 100,000. gave no reaction at all, whilst on the other side there was an infiltration of the size of a penny or even larger With some individuals the *reaction* to the bovine bacillus was stronger than the reaction to the human *bacillus*—a fact which *proved* that the deviations were produced not only by quantitative differences *in the* fluid injected but also by direct specific qualitative differences. *In the* course of these investigations it happened that Pirquet announced his discovery of the so-called "allergic reaction." The basis of this reaction is the "allergia"—that is to say, the changed capability of the organism with reference to reaction. He *discovered that persons who had once suffered the effects* of the poisons of the bacilli tuberculosis—that is to say, who had withstood a tuberculous infection or were at the time of observation still infected with tuberculin—showed the so-called cutaneous reaction if tuberculin was scratched into their skin, while, on the contrary, the skin of a normal person did not react at all to tuberculin.

Having read about this discovery which Pirquet published, Dr. Detre at once proceeded to verify the results which he had already *obtained* with the cutaneous reaction. For this purpose he used concentrated and *diluted* solutions of Koch's tuberculin, Deny's tuberculin, and Spengler's human and bovine filtrate, and finally, for the sake of comparison, carbolic acid solution of 0·5 per cent. strength, all according to the method of Pirquet. The first observations have already shown that the results of the cutaneous reactions entirely corresponded with those of the previously performed subcutaneous reactions, for persons who reacted to the subcutaneous injections of the filtrate of human bacilli gave a *stronger reaction to the same filtrate* also by the skin inoculation. These observations have also shown that the reactions had a quantitative value inasmuch as the diameter of the *local* reaction was in direct ratio to the dilution of the Koch tuberculin. Besides this the prevailing filtrates gave always stronger local reactions than the ten-fold dilution of Koch's tuberculin that was of the same concentration as the filtrate. This fact supported the assumption that the filtrate contained thermolabile toxins which Koch's tuberculin had lost during the process of preparation. One considerable drawback to the Pirquet *reaction* was that the great majority (90 or 95 per cent.) of adults gave it positively. From this it could be easily understood that it was of no considerable value. *Dr. Detre has investigated* whether there were any differences in the size of the local reaction according as the case was recent or of long standing, and his inoculations have shown that fresh cases were distinguished from old ones by the former having a greater sensitiveness to the filtrate. It was an open question whether there was any constant *difference* (caused by various degrees of sensitiveness to the poison) between the reaction of the Koch tuberculin and the filtrates. For elucidating this Dr. Detre has carried out special investigations in which he used (1) Koch's tuberculin in a concentrated form; (2) the filtrate from human bacilli; (3) the filtrate from bovine bacilli; and (4) the comparison *solution* of carbolic acid. These observations have shown that the single *infections* could be classified according to certain types of reactions. In the recent *progressive cases*, sensitive to the bacterial poisons, the local reactions following injections of the filtrate were larger than, or equal to, or nearly as large as the local *reactions due to* tuberculin. In chronic *cases the* reaction after the injection of the filtrate was inferior to that produced by Koch's tuberculin as regards size. Finally, in inveterate or very extensively spread cases the *reaction* might be entirely negative. This fact has been already mentioned by Pirquet.

The explanation of this difference *was that the* energetic reaction of the fresh cases was caused by their sensitiveness to the poison; at a later period the organism became tolerant of the labile poison and it was sensitive only to the protein; *finally, it lost its* sensitiveness even to the protein. In the investigations conducted by Dr. Detre the differences between the human and bovine infections were clearly shown in the local *reactions* produced by the two filtrates. He had some cases in which the local reaction due to the bovine bacillus *had* a diameter of 1 5 millimetres, whilst the local reaction due to the human bacillus had a diameter of 12 millimetres. On the other hand, there were cases, though *fewer in number*, in which the local reaction due to the human bacillus was considerably surpassed in size by the reaction due to the bovine bacillus. This fact proved that *there* were not only quantitative differences in certain cases. It was a *general* law of immunity that the organism reacted most distinctly to substances provoking the *immunity. And because* the allergic reaction was an immunity reaction it was *very probable that the cases* of bovine reaction were caused by the bovine bacillus and the cases of human reaction were caused by the human bacillus. In a certain number of cases, The acute paroxysms were due, he considered, to an accumulation of uric acid in the circulating blood and their sudden crystalline deposition around the affected joint. Besides his Lumleian lectures THE LANCET at different times published interesting communications from Dr. Garrod, amongst which we may mention especially a note on some chronic diseases of the alimentary canal and liver, also of the skin and articulations and their treatment by the long-continued use of small doses of sulphur given in the form of compound lozenges with cream of tartar, which had proved useful in his hands.[1] Another excellent paper contributed to these columns was on Aix-les-Bains and the value of its course in rheumatoid arthritis, gout, rheumatism, and other diseases.[2]

Although the study of gout and rheumatism occupied a large portion of his activities he by no means confined himself to these subjects. As we have said above, he took for the subject of his Goulstonian lectures the condition known as diabetes. Materia medica and therapeutics also took up much of his attention and his lectures upon the application of the science of chemistry to the discovery, treatment, and cure of disease which were delivered at University College Hospital and were published in THE LANCET of 1848, showed a knowledge of the interaction of chemistry, physiology, and pathology which in those days was rare. His text-book of "Materia Medica and Therapeutics," first published in 1855, was the work to which medical men and students through the greater part of the latter half of the last century were indebted for their standard text-book. When Garrod's book appeared he was professor of clinical medicine at University College, his chair including the subjects of materia medica and therapeutics. The book on its appearance ran to 280 pages and its value was hardly recognised from the first, as nearly ten years had elapsed before a second edition was called for, by which time its author had changed his allegiance to the King's College school. In 1874 a fourth edition was reached, and of this Dr. Buchanan Baxter acted as editor; the book was by that time an established success and 1886 saw the appearance of its eleventh edition, for which Dr. Nestor Tirard was responsible under the author's supervision, since Dr. Baxter, the first editor, had died. Sir Alfred Garrod was always interested in pharmacological and pharmaceutical matters and read papers before the medical and other societies on such subjects as the action of alkalies on alkaloids.

He was for some years a Physician Extraordinary to the late Queen Victoria who shortly before appointing him to this post conferred upon him the honour of knighthood at her Jubilee in 1887. On Dec. 6th of that same year he received the honour of being entertained at a complimentary banquet given by the members of his profession resident in his native town of Ipswich. His health was proposed by Dr. W. A. Elliston, physician to the East Suffolk and Ipswich Hospital, who, our readers will remember, was President of the British Medical Association when it met at Ipswich in 1900. Dr. Elliston, in referring to Sir Alfred Garrod's labours on the subjects of gout and rheumatic gout, concluded by saying that in his opinion the guest of the evening had done for the study of these allied diseases what Jenner had done for that of continued fever. Our knowledge of these two diseases, or should we say our consciousness of what gout and rheumatism are not, has grown greatly since the date of the appearance of the book in question, but when we reviewed the first edition in THE LANCET of Dec. 24th, 1859, we concluded as follows: "We do not hesitate to affirm that we never had the pleasure of reviewing a work from the perusal of which we have derived more advantage, and we can confidently recommend it as not only highly philosophical but likewise thoroughly practical."

In his later years Sir Alfred Garrod had wholly relinquished practice, and the increasing infirmities of old age prevented him from taking any share in the life of the profession or appearing in public. He, however, continued his experimental work on the subjects in which he was most deeply interested. He died quite peacefully from old age on Dec. 28th.

In 1845 he married Miss Elizabeth Anne Colchester, by whom he had six children, of whom three survive him. The eldest son, Alfred Henry Garrod, who was a distinguished biologist and F.R.S., died, aged 33 years, in 1879.

Dr. Nestor Tirard writes to us as follows concerning his old teacher:—"The death of Sir Alfred Baring Garrod at an advanced age removes one who in his prime had an enormous influence on the practice of medicine generally and on the development of therapeutics in particular. Before he became professor of materia medica and therapeutics at King's College he had published a text-book on this subject which for very many years was in the hands of most students and practitioners. He had also published a treatise on gout and rheumatic gout (rheumatoid arthritis), and the quotation from J. J. Rousseau on the title-page—

> 'Observez la nature, et suivez la route qu'elle vous trace'—

may well be taken as the keynote of his teaching and influence upon his students. In his wards and in his lecture room he continually referred to clinical observations whether relating to the symptoms of disease or to the remedial measures to be adopted. This tendency served to vitalise the details of materia medica and to encourage others to follow in his footsteps. Those who were fortunate enough to be his pupils instinctively felt that he was master of his subject and that they had only to name their difficulties to be supplied with illuminating explanations and illustrations. Some years after the calls of private practice had necessitated the relinquishment of his professorial duties and of hospital work I again had the advantage of meeting him frequently in connexion with the production of a new edition of his book on materia medica. In this he took an extremely active part, personally retaining the control of some of the sections, notably that dealing with the different mineral waters. When the British Pharmacopœia of 1898 was in course of revision Sir Alfred Garrod was chairman of the committee appointed by the Royal College of Physicians to make suggestions for omissions, additions, and alterations. His keen interest led him to preside, if I remember rightly, at all the meetings and the changes he advocated invariably found ready acceptance. Though he has outlived many distinguished pupils and associates, the influence of his work is still evident in many directions; his books may still be consulted with advantage and many of us will always feel proud of having been privileged to study under him."

Sir Dyce Duckworth has kindly sent us the following appreciation of the venerable physician's work. "Full of years, and regarded with esteem and affectionate regard by all who knew him, Sir Alfred Garrod has passed away after leaving a record of effective service in his profession which is known and appreciated wherever a scientific study of medicine is cultivated. His epoch-making disclosure in 1848 of the intimate relation between gouty disturbances and the behaviour of uric acid in the system formed a contribution of large importance to clinical medicine, one which has stimulated research in the same direction, and can never be ignored in discussing the still unsolved pathology of gout. All careful observers have had to acknowledge his facts, although different conclusions have been drawn from them by various investigators. As an exponent of organic and clinical chemistry Garrod's methods were exact and persistent. His laboratory was the human organism, ever the best for the bedside physician. His discoveries, whether in toxicology, pharmacy, or the improvement of the materia medica, were always designed in support of the *ars medendi*, for the benefit of the patient; and his success in practice was greatly due to this procedure, so that it was wont to be said of him that 'Garrod's medicines always did good.' We may cherish this recollection in these days when some of these matters are greatly neglected both in teaching and practice. After all, it was Garrod's *method* which made him an outstanding man amongst his contemporaries, the method of Hunter, to think first and then to try, for this gives the best indication in its possessor of the *mens medica*. With this, we, who knew him well, recognised his unfailing gentle kindness and sympathy and his genial interest in all matters relating to the profession. When the first Moxon medal was awarded by the Royal College of Physicians in 1891 it was felt that no worthier British recipient of it could be found than Garrod as fulfilling the requirements of 'distinguished research and observation in clinical medicine.' Sir Alfred Garrod's work and method have laid a responsibility on all who have entered into his labours to follow in the like path of duty and fruitful service for our common humanity."

---

[2] THE LANCET, May 4th, 1889, p. 869.

for less than 100 patients per day. In case of an epidemic the city will be allowed to use all the beds for the treatment of cases of one contagious disease only.

Montreal Maternity Hospital.

The sixty-third annual meeting of the friends and supporters of the Montreal Maternity Hospital was held recently in that city, Dr. T. G. Roddick being in the chair. In making a short address Dr. Roddick stated that the building was now practically free from debt owing to the energy of the ladies of the governing body and two or three good donations and bequests. The endowment fund was increasing gradually and now amounted to $6000. During the last hospital year 370 married women had been treated in the institution, and the report for the present year showed that the number had reached 440 Private patients had nearly doubled while the number of the unmarried patients had not increased. The hospital had conducted its financial affairs successfully during the year and there was a credit balance in the bank of $356.

A Simple Staining Method for the Gonococcus.

In the *Dominion Medical Monthly* Dr. J. G. Fitzgerald and Dr. E. H. Young of the Toronto Hospital for the Insane give a preliminary note on the above subject. It is simple and has been found useful by them and, as they state, must appeal to the busy general practitioner. The gonococcus is stained by an aniline basic dye and is decolourised by Gram's method. Their method is simply the application of Nissl's soapy methylene-blue solution without any counter-stain, the solution being made as follows: methylene blue B. patent, 3·75; Venetian soap, 1·75; and distilled water, 1000. The smears, which should be made on slides (and care must be taken to have them as thin as possible), are fixed in the air and then stained (without heating) for one minute with Nissl's solution, washed, blotted, and are ready for examination with the oil-immersion lens.

Is Toronto to Have a New Medical School?

McMaster University is a denominational institution in Toronto belonging to the Baptists. At a recent Baptist convention held at Woodstock the board of governors and Senate of McMaster University submitted to that convention a report recommending the project of establishing a medical faculty in connexion with that university. The University of Toronto, with which McMaster University is not affiliated, has a strong medical faculty, their freshmen numbering this year about 230. Probably McMaster University considers this is too large a class even of freshmen for one university to handle successfully and that it could attract to itself a considerable proportion of the medical student body attached to the Provincial University. However, as yet no definite steps have been taken along the lines suggested by the Senate and board of management of McMaster University.

Dec. 20th, 1907.

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

A Centralised Ambulance System.

ALTHOUGH New York was the first city in this country to adopt the army ambulance as a means of conveying the sick in civil practice there has never been a well-organised system of ambulance service. Each hospital has had its own ambulances and the police officials have summoned them in cases of emergency. The police authorities have created districts for the different hospitals to which the ambulances of that hospital have been limited, except on occasions of great emergencies. The Municipal Hospital Commission recently devoted a session to conferences with representatives from the various hospitals for the purpose of obtaining information in regard to the working of the present system. The conclusion was that there should be a central ambulance station corresponding to the fire headquarters to which all ambulance calls should come and through which they should be assigned to the various hospitals.

Flies the Cause of High Summer Mortality.

The Merchants' Association Committee on Pollution of the Waters has published the report of the bacteriologist of the Water Bureau of New York city on investigations to determine the influence of river flies in conveying the germs of disease to the people of the city. It appears that a large number of fly-traps were placed underneath the piers of the city which were daily visited and the flies collected and submitted to examination by counting and the best bacteriological methods. The examination showed that a "South Street house-fly" carried 100,000 bacteria. At the same time a careful investigation was made of the sanitary condition of the water front of the entire city. It was found that sewage abounded and that these flies were thickest at the point where there was the most sewage and that where it was scarce the flies were few in number. The flies were found to carry less bacteria in the early season than during the hot term. The tabulations and diagrams of the report show that the time of the greatest prevalence of flies in 1907 was the three months beginning July 1st and ending Oct. 1st. A record of the deaths from intestinal diseases shows that the deaths from these diseases rose above the normal at the time at which the flies became prevalent, culminated at the same high point, and fell off at the time of the gradual falling-off of the prevalence of the insect. The report concludes with the assertion that this so-called harmless insect is one of the chief sources of infection, which in New York city causes annually about 600 deaths from typhoid fever and about 7000 deaths yearly from other intestinal diseases.

The Plague on the Pacific Coast.

It appears from a report of a commission acting under the authority of the American Medical Association that the plague has not been exterminated from the Pacific coast. Since August 108 cases have been verified, of which 65 died. There was in addition a large number of suspected cases. The first recognised case occurred in 1900, but suspected cases had from time to time been previously reported. The effect of the great fire following the earthquake seems to have been to extend the disease by scattering the rats and the inoculation of ground squirrels, though an enormous number of rats were killed in the fire. Another feature of the fire which increased the spread of the plague was the insanitary conditions which followed. The commission states that the sewer system was almost completely broken up, water was scarce, people were compelled to cook and almost to live in the streets, garbage was thrown about promiscuously, refugees were crowded together in tents and later in shacks, and these camps became filthy. Some of these camps are said to have become hives of dirty humanity and to have swarmed with rats and fleas. That the plague is now widely scattered among the cities of the Pacific coast is evident and the measures taken to arrest and exterminate it seem altogether inadequate owing to the indifference of the people and the local authorities outside of San Francisco and Oakland where thorough anti-plague work is being done. The commission concludes that the continued existence of such a disease over such an area, and for the time during which it is evident that the infection has existed here, would seem to make the infection a subject for national consideration.

State Prohibition of Nostrums.

The State of Massachusetts, through its board of health, is rigidly enforcing its laws against the sale of noxious nostrums, one of the most conspicuous of which is cocaine in various forms. The law, which went into effect on Sept. 1st, 1906, provides—

> That it shall be unlawful for any person (including physicians) to sell or to expose or offer for sale or to give or exchange any patent or proprietary medicine or article containing cocaine or any of its salts or alpha-eucain or beta-eucain or any synthetic substitute of the aforesaid.

A large number of preparations, generally advertised as remedies for catarrh or diseases of the throat, have been condemned by the board of health, and their proprietors brought into court and convictions obtained. The effect of this law in the suppression of these injurious and often dangerous nostrums has awakened a wide-spread interest and other States are certain to take similar action.

Tuberculosis in Herds of Cattle.

The New York State Veterinary College reports through its expert bacteriologist that 72 per cent. of the herds of the State of New York are tuberculous. This expert has made a careful study of meat inspection and states that although the citizens of the State are now thoroughly protected against Chicago and Western beef by the pure food and meat inspection laws, the markets of the State are loaded with domestic beef, a large percentage of which is infected with the tuberculous germ. The statistics collected by Professor Moore show that of 364 herds examined 72·3 per cent. included tuberculous animals. Estimates based on these

year's total was £6170. The movement is now very well organised and works smoothly. The greatest contribution was made by the police whose collection through their band was £605.

Women's Hospital, Melbourne.

A fund was recently started by the Lady Mayoress of Melbourne for extension of buildings at the Women's Hospital. It is now announced that the fund has reached £5000, which enables the committee to claim a further sum of £5000 promised by the Victorian Government.

The Protection of Infant Life.

The Victorian Government has introduced a Bill dealing with this subject. In 1901 there were 525 registered nurses in charge of 779 children and the deaths were 12·7 per cent. There were 69 police inspectors. In 1902 the percentage of deaths was 15·1; in 1903, 13·7; in 1904 9·7; in 1905, 7·8; and in 1906, with 583 nurses and 974 children, the deaths were 10·9 per cent. The number of police inspectors had increased to 124. In introducing the new measure the Chief Secretary said the great difficulty was to induce a better class of women to register as nurses. He thought that this would be overcome by taking the inspection out of the hands of the police. In South Australia the Act was administered by an honorary council and in New South Wales by the chief officer of charitable institutions. Under the new Bill the control would be placed in the hands of the department for neglected children. That department had honorary committees chiefly of ladies throughout Victoria who were prepared to keep a supervision over the children. The payment of lump sums to nurses for taking charge of children was to be forbidden absolutely. The parents could pay a sum to the department but nurses would receive weekly payments. For the first 12 months the payment would be 10*s.* per week. After that the rate might be reduced to 7*s.* per week. There would be two or three female inspectors appointed and an extra £1000 per annum would be required for payments to medical men for extra supervision. Particulars of a child's parentage would be kept and revealed only by order of the Minister. In certain circumstances a medical certificate of death would be accepted instead of the statutory coroner's inquiry as at present. Under the new Bill provision is also made for the establishment of maternity homes.

Public Health in Queensland.

The annual report of the Commissioner for Public Health, Queensland, was presented to Parliament last month and covers the work to June 30th. Dr. B. B. Ham refers at some length to the inadequacy of means of domestic storage for meat and milk and remarks: "The food 'safe' and larder may often be labelled as infected domestic areas." Ophthalmia is noted as an increasing danger to children in western Queensland and the need for domestic care and school inspection is insisted upon. The inspection of foodstuffs was being carried out by the department as, with the exception of the Brisbane city council, local authorities continued to display great apathy. A marked improvement was generally manifested in existing conditions compared with those of a few years ago.

Adelaide Children's Hospital.

The thirty-first annual meeting of the friends and supporters of this institution was held on Oct. 31st under the presidency of the Governor of South Australia (Sir G. R. Le Hunte). The annual report showed that 593 in-patients had been treated with 36 deaths, that 563 surgical operations had been performed, and that the out-patient attendances totalled 8161. The revenue of the institution was well maintained and the hospital benefits largely from a legacy of £200,000 under the will of the late Mr. T. Martin. The share of revenue available from this fund will permit extension of the hospital buildings in the near future and the committee had already been able to make some additions and renewals. The officer-bearers were re-elected on the motion of the Bishop of Adelaide.

Transposition of Viscera.

A patient recently died in the Queenstown Hospital, Tasmania, from acute nephritis. The medical officer noted during life that the heart was transposed and a post-mortem examination revealed complete transposition of all the viscera. The deceased was a boiler-maker and had always enjoyed vigorous health.

Nov. 30th, 1907.

Obituary.

SIR ALFRED BARING GARROD, M.D. LOND., F R C.P. LOND., F.R.S.,

CONSULTING PHYSICIAN, KING'S COLLEGE HOSPITAL.

BY the death of Sir Alfred Baring Garrod, which occurred on Dec. 28th, 1907, at the advanced age of 88 years, the profession of medicine in the United Kingdom loses one of its oldest and best known members.

Alfred Garrod was born in 1819, at Ipswich, and received his early education at the Ipswich Grammar School, whence, after serving an apprenticeship to Mr. Charles Hammond, surgeon to the East Suffolk Hospital, he proceeded to University College and the hospital attached thereto. He graduated at the University of London, being placed first in medicine at the examination for the degree of M B. in 1842 and also at that for the degree of M.D. in the following year. He became a Member of the Royal College of Physicians of London in 1851, was elected a Fellow in 1856, served as Senior Censor in 1887, and as a Vice-President in 1888. In the year following his election as Fellow he was the Goulstonian lecturer, the subject of his lectures being Diabetes. In 1858 he received the honour of being made a Fellow of the Royal Society of London. In 1883 he delivered the Lumleian lectures at the Royal College of Physicians of London, his subject being Uric Acid: its Physiology and its Relation to Renal Calculi and Gravel. As regards his career as a practising physician, he was elected assistant physician to University College Hospital in 1847 and full physician and professor of therapeutics and clinical medicine in 1851. In 1863 he became physician to King's College Hospital as well as professor of materia medica and therapeutics and clinical medicine at the college. These posts he held until 1874 when he was made consulting physician.

Sir Alfred Garrod is best known to the present generation of medical men by his work upon materia medica, originally published in 1855, and by his researches into the nature of the pathological conditions which are associated with the terms "gout" and "rheumatics." It was in 1847 that he discovered the presence of uric acid in the blood of gouty patients and a paper by him upon this subject was communicated to the Royal Medical and Chirurgical Society of London on Feb 8th, 1848, by the late Dr. C. J. B. Williams. The paper was received with great interest and Dr. Williams pointed out that although he himself had for years taught that the presence of lithic acid in the blood was the cause of gouty manifestations yet the demonstrative proof that this acid did exist in the blood in such circumstances was entirely due to Dr. Garrod. The subjects of gout and rheumatism continued to interest Dr. Garrod for many years and in 1859 he published his well-known work upon the Nature and Treatment of Gout and Rheumatic Gout. This latter disease he proposed should in future be called rheumatic arthritis, a designation which is now giving way to arthritis deformans. It was in this book that he drew attention to the use of the lithium salts for gouty conditions. In 1883 Dr. Garrod delivered the Lumleian lectures as stated above. In these lectures he first discussed the probable seat of origin in the body of uric acid, alluding naturally to his own discovery of that substance in the blood in 1847. He also considered the urines of all classes of the animal kingdom with which he had made many experiments, as he had also done with their blood by his now classical thread test. He entered very fully into the whole matter, concluding that the evidence was strongly in favour of the true renal origin of uric acid. He then discussed the bearing of his views on calculus formation and the influence of different diets upon that disorder, and finally described experiments which he had made to check the late Sir (then Dr.) William Roberts's well known work on the Solubility of Uric Acid in Alkaline Carbonates and Other Reagents. This excellent course of lectures proclaimed him a patient investigator and a clear thinker on a subject in which he was keenly interested. In these lectures he did not expound his views on uric acid in relation to gout but it is interesting to recall them as he expressed them elsewhere He held that with lessened alkalinity of the blood there was increased uric acid owing to faulty elimination and that this diminution of alkalinity caused the deposition of the sodium urate, which required a more alkaline medium to hold it in solution.

SIR ALFRED BARING GARROD, M.D. LOND., F.R.C.P. LOND., F.R.S.,
CONSULTING PHYSICIAN, KING'S COLLEGE HOSPITAL.
(*From a photograph taken about 1887.*)

he was urged by some of his colleagues to apply for that post but could not be induced to do so. He was for some years medical officer of health of the borough of Wrexham and rendered valuable services in the advancement of sanitary science and public health. He was a former president of the North Wales branch of the British Medical Association and his year of office was a most successful one. He had high ideals of medical ethics and his advice was always in consonance with the best traditions of the duties of members of the profession to the public and to one another. Not the least of his characteristics were his modesty and unassuming manner. To all who knew him he was the embodiment of uprightness of conduct and he lived and died a pattern not only of a good physician but of an English gentleman.

THOMAS ANNANDALE, M.D. EDIN., F.R.C.S. ENG. AND EDIN., D.C.L. DURH.,

REGIUS PROFESSOR OF CLINICAL SURGERY IN THE UNIVERSITY OF EDINBURGH.

IT is difficult for those who knew Professor Annandale and frequently saw him going to, or returning from, the infirmary to realise that his figure has finally disappeared from the streets of Edinburgh. Few men were more widely known to sight by the general public. No one would have guessed that he would so suddenly have been removed from the sphere of active surgical work. On Thursday afternoon, Dec. 19th, 1907, he operated in the infirmary, dined at home, retired early as was his habit, and on Friday morning was found dead in bed. That this was a great shock to his colleagues and professional friends can easily be realised. There had been no hint of indisposition of any kind; no man seemed to carry his years more easily; no man appeared more equable or seemed to work with greater ease; and yet within the space of a few hours he passes from the operating theatre to the final bourne. That his more intimate friends in the Senatus and outside should have been stunned by the occurrence is not difficult to realise.

Professor Annandale was born in November, 1838, so that he had only reached his sixty-ninth year. He was a native of Newcastle and made his first acquaintance with surgery in the hospital of that town and in his father's practice. In 1856 he became a student of medicine in Edinburgh. He graduated in 1860 and received a gold medal for his thesis on the Injuries and Diseases of the Hip-joint. In 1859 he obtained the M.R.C.S. Eng. Immediately after graduation he became house surgeon to Professor Syme, a post which he held for 12 months. In this position he so impressed his great master with his surgical capacity that Syme made him his private assistant. He occupied this important position from 1861 to 1870, when Syme died. He accompanied his master to operations all over the country and when he became a candidate for an honorary surgeoncy in the infirmary he had Professor Syme's warm support, a support which no doubt weighed heavily in determining his appointment. Before this appointment he had been awarded the Jacksonian prize for his essay on the Malformations, Diseases, and Injuries of the Fingers and Toes and their Surgical Treatment. In 1871 he became a full surgeon to the infirmary and became entitled to lecture on clinical surgery. He was a popular lecturer and always drew a large number of students to his lectures and his ward clinics. When in 1877 Professor (now Lord) Lister resigned the chair of clinical surgery Mr. Annandale was appointed his successor. This post he filled until his death. Professor Annandale's professional life was thus spread over a very remarkable period in the history of surgery. He began surgery at a time when expertness and dexterity, nerve, and courage were absolutely necessary to the surgeon. He had as his master in these departments the great Syme. Meanwhile Lister was slowly, laboriously, but surely laying the foundations of a scientific side of surgery that was destined to revolutionise the whole practice and to transfer technical dexterity with the operating knife to dexterity in asepsis. Following upon this came abdominal surgery where patient labour in the depths of that cavity led to the great victories gained in this region. Professor Annandale's 45 years of active surgical work thus covered a time marked by the beginning, the growth, and the complete success of a revolution in his own department.

In virtue of his surgical instinct and his great experience his opinion was often invaluable; his dexterity, resourcefulness, and nerve never forsook him. He was known wherever Edinburgh graduates were placed; he was proud of his friends and former students dotted all over the globe; he used to boast that he had operated in three, if not in four, continents. He was a member of various learned societies and he was Surgeon-General to H.M. the King's Bodyguard for Scotland—the Royal Archers. In all University matters he took the warmest interest, especially in all matters affecting the comfort, or well-being, or interests of the students. He took a prominent part in connexion with the Students' Union and with the Athletic Club and other projects which he regarded as for the good of the students. He was much liked by them; indeed, their liking amounted to affection. He was a kind-hearted, friendly, and genial influence in Edinburgh medical life.

Professor Annandale married in 1874 a daughter of the late Mr. William Nelson, of the well-known publishing firm. There was a family of three sons and three daughters. The funeral took place on Dec. 23rd from St. John's Episcopal Church to the Dean Cemetery.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Professor Adalbert Tobold, *privat-docent* of laryngology and rhinoscopy in the University of Berlin. Dr. Oskar Lassar, *privat-docent* of dermatology and syphilis in the University of Berlin.

Medical News.

UNIVERSITY OF CAMBRIDGE.—The following appointments have been made: Senior Demonstrator in Anatomy, Dr. W. L. H. Duckworth; Junior Demonstrator in Anatomy, Dr. D. G. Reid. The following has been examined and approved for the degree of Master of Surgery:—

E. W. Sheaf, Downing.

At examinations for Medical and Surgical Degrees held in Michaelmas Term, 1907, the following candidates were successful:—

SECOND M.B. EXAMINATION.

Human Anatomy and Physiology.—R. L. Barker, B.A., Caius; F. S. Bedale, Clare; J. P. Benskin, Christ's; D. C. Bluett, Emmanuel; C. H. B. Booth, King's; E. G. S. Cane, B.A., Jesus; R. G. Canti, B.A., King's; R. F. P. Cory, B.A., Caius; H. T. Depree, B.A., Clare; C. Ede, King's; R. Ellis, B.A., Catharine; A. G. Evans, Trinity; J. T. Fox, B.A., Sidney Sussex; A. W. Gaye, B.A., Caius; A. C. Gemmell, B.A., Trinity; R. W. B. Gibson, B.A., Jesus; H. K. Griffith, B.A., Trinity; L. S. M. Habich, B.A., St. John's; J. B. Hance, Christ's; L. C. D. Irvine, Emmanuel; A. C. Jepson, B.A., Pembroke; J. C. John, King's; L. F. G. Lewis, B.A., Christ's; J. R. Marrack, St. John's; W. G. Marsden, Emmanuel; C. C. Messiter, B.A., C. G. H. Moore, B.A., and P. A. Opie, B.A., Caius; G. M. Parker, B.A., Emmanuel; A. B. Pavey-Smith, Clare; J. W. Pigeon, Christ's; H. B. Pope, Caius; P. A. Powell, B.A., Trinity; R. A. Ramsay, Caius; E. Rayner, Pembroke; W. D. Ross King's; A. Sandison, B.A., Trinity; F. P. Saunders, B.A., Clare; W. Shipton, B.A., Emmanuel; I. Singh, B.A., Pembroke; G. N. Stathers, Trinity; F. J. Thorne, B.A., Jesus; P. B. Wallis, B.A., Pembroke; and F. H. Watson, B.A., and J. B. A. Wigmore, Caius.

THIRD M.B. EXAMINATION.

Part II., Surgery, Midwifery, and Medicine.—J. B. Banister, M.A., Jesus; J. W. H. Bean, B.A., H. Selwyn; E. Beaton, B.A., Caius; H. S. Berry, M.A., Clare; C. W. Bowle, B.A., Trinity; D. W. A. Bull, B.A., Caius; B. P. Campbell, B.A., Clare; J. R. C. Canney, B.A., Christ's; H. B. Carlyll, B.A., St. John's; R. G. Chase, B.A., Trinity; R. N. Chopra, B.A., Downing; F. Clayton, B.A., Trinity; H. N. Coleman, B.A., Christ's; G. H. Davy, B.A., Caius; A. W. C. Drake, B.A., Pembroke; N. M. Fergusson, B.A., Magdalene; G. B. Fleming, B.A., King's; R. L. Gamlen, B.A., Caius; G. Graham, B.A., Trinity; F. W. W. Griffin, B.A., King's; O. Heath, B.A., Trinity; B. B. Hinde, B.A., Emmanuel; A. F. Jackson, B.A., Peterhouse; K. A. Lees, B.A., King's; S. G. Luker, M.A., Pembroke; M. W. B. Oliver, B.A., Trinity; E. V. Oulton, B.A., Christ's; B. H. Palmer, B.A., Pembroke; W. G. Parkinson, B.A., Emmanuel; B. A. I. Peters, B.A., Jesus; J. H. Ryffel, M.A., Peterhouse; L. Shingleton-Smith, B.A., St. John's; E. Slack, M.A., Pembroke; B. C. Sparrow, B.A., Trinity; H. H. Taylor, B.A., Pembroke; C. H. Treadgold, M.A., Clare; F. B. Treves, B.A., Caius; P. J. Verrall, B.A., Trinity; K. M. Walker, B.A., Caius; and A. Wilkin, B.A., King's.

LONDON SCHOOL OF TROPICAL MEDICINE.—The following students of the above school successfully passed the examination in Tropical Medicine held at the end of the twenty-fifth session, October to December, 1907:—

*Graham U. Smith, M.B., D.P.H., M.R.C.S., L.R.C.P.; *Major W. Westropp White, I.M.S., M.D., M.Ch., M.A.O.; *H. L. Deck, M.R.C.S., L.R.C.P.; *J. Cross, M.B., Ch.B.; G. H. Hustler, M.B., Ch.B. (Colonial Service); Captain M. J. Quirke, I.M.S., M.B., Ch.B.; F. L. Henderson, M.R.C.S., L.R.C.P. (Colonial Service); T. L. Craig, M.B., B.Ch. (Colonial Service); W. R. Larbalestier, L.R.C.P., M.R.C.S., L.D.S. (Colonial Service); A. E. Oakeley, M.R.C.S., L.R.C.P.; W. B. Gibson, F.R.C.S., L.R.C.P.; F. A.

SIR ALFRED BARING GARROD, M.D. LOND., F.R.C.P. LOND., F.R.S.,
CONSULTING PHYSICIAN, KING'S COLLEGE HOSPITAL.
(*From a photograph taken about 1887.*)

practitioner present worked appropriately by making President for the evening Dr. R. Palgrave Simpson who, after 40 years' practice in Weymouth, is shortly retiring. An excellent dinner was served and after the toast of "The King" allusion was made to the approaching departure of Dr. Simpson and his health was enthusiastically drunk. In returning thanks the chairman recalled the fact that he was the sole surviving representative of the old local book club which was already defunct before the arrival in Weymouth of any other medical man present. The remainder of the evening was occupied by an excellent programme of music and at the close of a very pleasant gathering the club congratulated itself on a most propitious "send-off."

Royal Microscopical Society.—At the Royal Microscopical Society on Dec. 18th, 1907, Mr. J. E. Barnard showed a number of luminous bacterial cultures in test-tubes and flasks. He said that the bacteria were all of marine origin and that they were cultivated in an ordinary gelatine medium to which certain salts had been added. At first he used the chlorides of sodium, potassium, and magnesium in proportions resembling those in which they occurred in sea water, but he afterwards found that quite different salts, such as phosphate of sodium, were equally suitable provided the solution was isotonic to sea water. The light emitted was very nearly monochromatic, being included almost entirely between the F and G lines of the solar spectrum. The curve of light energy therefore rose and fell very abruptly, forming quite a contrast to the gradual rise and fall of the similar curve for sunlight. Before leaving this subject we may mention that directions for the cultivation of these organisms will be found in The Lancet of Oct 13th, 1900, p. 1087. A paper by Mr. E. M Nelson on Gregory and Wright's Microscope was read by the secretary. This microscope was made about 1786 by the firm of Gregory and Wright who were probably the successors of Benjamin Martin. It was a stage focusser and was described as an "aquatic microscope" —i.e., one in which the object-glass moved over the object instead of the object moving under the object-glass. Some of the features of Oberhäuser's drum microscope, made in 1835, were described. Another paper by Mr. Nelson, also read by the secretary and entitled "A Correction for a Spectroscope," suggested that the telescope of a spectroscope should have its object-glass pivoted so that the rays emerging from the prism might be received by it at varying angles. The secretary also read a paper entitled "Some African Rotifers," by Mr. James Murray who was at present on his way to the Antarctic regions. Mr. Eustace Large exhibited as polariscope objects a variety of sections of selenite illustrating the phenomena of "twinning." They were shown both in table polariscopes and under low powers of the microscope; the visible effects consisted of brilliantly coloured geometric patterns.

BOOKS, ETC., RECEIVED.

Perlado. Páez y Ca (Sociedad en Comandita) (Sucesores de Hernando), Arenal, 11, 7 Quintana, 31, Madrid.

Diagnóstico y Tratamiento de las Enfermedades de las Vías Urinarias. Lecciones elementales. *Por Alberto Suárez de Mendoza*, Profesor de Enfermedades de las Vías Urinarias en la Facultad de Medicina de Madrid. *Price* 15 pesetas.

Wilson, Effingham, 54, Threadneedle-street, London, E C.

A Practical Guide to the Death *Duties* and to the Preparation of Death Duty Accounts. By Charles Beatty, Solicitor, of the Estate Duty Office, *Somerset House.* Second edition (Revised and enlarged). Price 4*s.* net.

Wright and Potter Printing Company, State Printers, 18, Post Office-square, Boston.

Twenty-eighth Annual Report of the State Board of Health of Massachusetts. *Price not stated.*

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

Attenborough, Wilfrid, M.R.C.S., L.R.C.P. Lond, has been appointed House Physician at Addenbrooke's Hospital, Cambridge.

Byrne, P. Kevin, M.D., M.R C.P. Lond., has been appointed Assistant Physician to the London Temperance Hospital.

Clark, Robert V., M.B. Edin., has been appointed Medical Officer of Health of Leeds.

Corbin, H. H., M.R.C.S., L.R.C.P. Lond., D.P.H., has been appointed Medical Officer of Health of Stockport.

Dimock, Horace, M.B., B C. Cantab., has been appointed House Surgeon at Addenbrooke's Hospital, Cambridge.

Hailstone, J. E., M.R.C.S., L.R.C.P. Lond., has been appointed Assistant House Surgeon at Addenbrooke's Hospital, Cambridge.

Hawes, Ivon Henry Skipwith, M.B., B.S. Durh., has been appointed Medical Officer for the Wick District by the Chipping Sodbury (Gloucestershire) *Board of Guardians.*

Higgs, F. W., M.B, B.S. Lond., M.R.C.P. Lond., has been appointed *Medical Registrar to St. George's Hospital.*

Hosford, J. Stroud, F.R.C.S. Edin., has been appointed Assistant Ophthalmic *Surgeon* to the London Temperance Hospital.

Hourigan, W. P., L.R.C.S. Irel., L.R.C.P. Edin., has been appointed Certifying Surgeon *under the Factory and Workshop Act* for the Freshford District of the county of Kilkenny.

Hunter, William, M.D., *C.M. Edin., F R C.P. Lond.*, has been appointed Physician to Charing Cross Hospital.

Jameson, R. C., M.B., C.M. Edin., has been appointed Honorary Clinical Assistant to the Eye and Ear Department *of* the Leeds Public Dispensary.

Johnson, L. Capper, M.B. Lond., Ch.B. Vict., M.R.C.S., L.R.C.P. Lond., has been re-appointed Honorary Anæsthetist to the Surgical Department of the Leeds Public Dispensary.

Legge, J. H, M.B., B Sc. Lond., has been appointed Honorary Anæsthetist to the Dental Department of the Leeds Public Dispensary.

MacHale, P. J., L.R.C.P. & S. Irel., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Belmullet District of the county of Mayo.

Maclure, W. J., M.B., B.S. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Conisborough District of the county of York.

O'Grady, *F. R.* L.R.C.S. Irel., L.K.Q.C.P. Irel., has been appointed Certifying Surgeon under the Factory and Workshop Act for the *Swineford District of the* county of Mayo.

Quick Hamilton Ernest, B.Sc., M.B., B.S. Lond., L.R.C.P., M.R.C.S., *has been appointed* House Surgeon at the Swansea Hospital.

Sandilands, J. E., M.D. Cantab., M.R.C.S., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Winchester *District of the county of Hants.*

Spriggs, N. I. M.R.C.S., L.R.C.P. Lond., has been appointed Certifying Surgeon *under the Factory* and *Workshop* Act for the Shrewsbury District of the county of Salop.

Sutcliffe, Amelia, *M.B., Ch.B. Edin., has* been re-appointed Honorary Clinical Assistant to the Leeds Public Dispensary.

Thomson, May, *L.R.C.P. & S. Edin., L.F.P.S. Glasg.*, L.M. Dub., has been re-appointed Honorary Clinical Assistant to the Leeds Public Dispensary.

Ward, J., M.R.C.S., L.S.A., has been appointed Certifying Surgeon under the *Factory* and Workshop Act *for the Leamington District* of the county of Warwick.

Whalley, Frederick, M.B., Ch.B. Leeds, *has been appointed* Honorary Anæsthetist to the Dental Department of the Leeds Public Dispensary.

Whitehead, Francis Henry, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer to the *Post Office* at *Battersea*, S.W.

Wilson, E. Allan, M.D. Lond., M.R.C.S., L.R.C.P. Lond., has been re-appointed Honorary Anæsthetist to the Dental Department of the Leeds Public Dispensary.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Bootle Hospital for Infectious *Diseases.*—Resident Medical Officer unmarried. Salary £100 per annum, with board, washing, and apartments.

Brighton, Sussex County Hospital.—Third House Surgeon, unmarried. Salary £80 per annum, with board, residence, and washing.

Burslem, Borough of.—Medical *Inspector* of Children in Public Elementary Schools (female). Salary at rate of £150 per annum, rising to £200.

SIR PATRICK HERON WATSON, LL D. EDIN., M.D. EDIN., F.R.C.S. EDIN., HON. F.R.C.S. IREL.,

HONORARY SURGEON IN SCOTLAND TO THE KING.

THE medical profession in Scotland has lost one of its most prominent members by the death of Sir Patrick Heron Watson of Edinburgh. The sad event was not unexpected, for he had been in poor health for some years and during the last six months he had been seldom out of doors. Heart failure was the cause of death and he passed away on Dec. 21st, 1907, at his residence in Charlotte-square, Edinburgh.

Patrick Heron Watson was a son of the late Rev. Charles Watson, D.D., parish minister of Burntisland, Fifeshire, and was born on Jan. 5th, 1832. In 1853 he graduated as M.D. at the University of Edinburgh; in the same year he also became a Licentiate, and two years later a Fellow, of the Royal College of Surgeons of Edinburgh. On the outbreak of the Crimean war he joined the Army Medical Corps as staff assistant surgeon, afterwards being assistant surgeon in the Artillery and Royal Horse Artillery. For six weeks after reaching the Crimea he was invalided with typhus fever and then was attached to the battery at Balaclava, where he had dysentery and was seriously ill. For his services in the war he received the Crimean, Turkish, and Sardinian medals On his return home Dr. Watson commenced the teaching of surgery at High School Yards, Edinburgh; was subsequently elected lecturer on systematic and clinical surgery at the school of the Royal College of Surgeons of *Edinburgh*; and was then appointed surgeon to the Royal Infirmary, of which he continued a consulting surgeon. He was also consulting surgeon to Leith Hospital and *surgeon at Chalmers Hospital, Edinburgh. He* represented the Royal College of Surgeons of Edinburgh on the General *Medical Council from 1882 to 1906*, succeeding the late Mr. James Spence and being himself succeeded by Dr. *J. W. B. Hodsdon*. He was also a member of the Edinburgh University Court, a curator of patronage, and an honorary Fellow of the Royal College of Surgeons in Ireland. In 1884 he received the distinction of LL.D. from the University of Edinburgh; he was an honorary surgeon in Scotland to Queen Victoria and was honorary surgeon to the King. He was a Chevalier of the Order of Carlos III. of Spain, was a surgeon of the 5th Volunteer Infantry Brigade, and held the Volunteer Decoration. He was also a Deputy Lieutenant of the City of Edinburgh No surgeon was more widely known in Scotland, and his services as operator or consulting surgeon were in request in difficult cases all over the country. In July, 1903, he received the honour of knighthood. As President of the Royal College of Surgeons of Edinburgh he took a leading part in the celebrations of the quatercentenary of the College in 1905. That was the second occasion upon which he had held the position of President, the previous occasion being in 1878. His principal published works, with their dates, were "The Modern Pathology and Treatment of Venereal Disease" (1861) and "Excision of the Knee-joint" (1867) He also edited the late Professor James Miller's "System of Surgery." He married a daughter of Professor Miller to whom he acted as assistant for several years after his return from the Crimea. His wife predeceased him several years ago but he is survived by two daughters and two sons.

For the following appreciation of the life and work of the deceased we are indebted to Mr. Rutherford Morison of Newcastle-on-Tyne:—

"The death of Sir Patrick Heron Watson must leave in the minds *of his old* pupils a sense of painful bereavement, for his was a unique and impressive *personality. To his old* house surgeons he was a hero they worshipped, for to work with him was an inspiration which *could not fail to leave its* mark on the least plastic of men. It was my privilege to act as his resident *surgeon in the year 1875 in the old Royal* Infirmary at Edinburgh. His reputation was then made and he was universally recognised as one of the foremost operators in the world. He had already performed most of the abdominal operations which are now common property, and had excised the spleen, the kidney, ovarian and uterine tumours, and portions of intestine at a time when it was thought impossible to bring such undertakings to a successful issue. He had then also excised the whole larynx for malignant disease and had performed several successful thyroidectomies by a new *and* original method, since generally adopted, of ligaturing the arteries of supply before interfering with the gland itself. It has indeed often seemed to me, in looking back to the time when I was working with him, that most of what he did then is the operative surgery of to-day and was at least 20 years in advance of that period. That he has not received the recognition as a surgical pioneer he deserved is due solely to the fact that he failed to avail himself, as so many of the strongest and ablest men of that generation did, of the revolution in the treatment of wounds which was being brought about by Lord Lister. It was impossible for him to accept the new principles in the whole-hearted fashion necessary to carrying out the details with success. Operations such as lateral lithotomy, excision of the jaw and tongue and rectum, which he performed with a skill I never saw equalled, gave brilliant results; many others, more dependent on attention to antiseptic detail, were in spite of his diagnostic ability and manipulative dexterity doomed to failure.

At the time previously mentioned (1875) and for twenty years afterwards his whole time was busily occupied by professional work. In addition to the largest surgical practice in Scotland, *consulting* and operating, he constantly had medical patients with all sorts of ailments under his care, and how he managed to get through all he had to do was a mystery to his friends. Yet he never appeared to be in a hurry and always found time to spare for his hospital work and surgical lectures and private pathological museum. Patients came from all parts of the world to consult him and with such faith it was a common saying in Edinburgh 'that most of them would rather be killed by Dr. Watson than cured by anyone else.' Small wonder that patients trusted him. Everyone who saw him felt at once his strength and capacity. Every surgeon must have experienced after finishing an anxious and difficult operation doubt as to whether he did the best that could be done to meet some sudden and unforeseen emergency, but nobody ever doubted this of Sir Patrick Heron Watson. He seemed to have considered every possibility beforehand, and any difficulties were so quietly met and so methodically dealt with that they could not appear, except to the initiated, as difficulties at all. There was a stronger individuality about Dr. Watson than about anyone else I *have* known and though this cannot be conveyed to strangers his *old house* surgeons will remember his military walk, his correct attire, his neat, plainly-written notes, his method of interviewing and prescribing for out-patients, his courteous manners, his independence of character, and his ready command of language, which might not always be to their satisfaction but was always *to their* lasting advantage, as peculiarly his own. There are many of us who will revere these memories for we loved the *man*."

JOSEPH LLEWELYN WILLIAMS, M.B., C.M. EDIN., M.R.C S. ENG., L.S.A.

THE *medical* profession in Wrexham and district has lost one of its kindest and most loyal colleagues in the lamented death of Dr. J. Llewelyn Williams of Holt-street House, which occurred somewhat suddenly on Friday evening, Dec. 13th, 1907, from heart disease. By his death the profession suffers a severe loss and to those who knew him best his sterling qualities and steadfast friendship will ever remain as cherished memories. Dr. Williams was the son of the late Dr. Edward Williams, who died in 1893 after many years of extensive practice in Wrexham and the surrounding neighbourhood. Dr Llewelyn Williams, like his father, was an ideal "family doctor." His gentle voice, honest, grave eyes, and sympathetic personality did much to cheer and help those in suffering and sorrow; always patient and ready to hear and to sympathise with their minor troubles and worries, he never left a bedside without a cheery word of help and comfort for his patient. Dr. Williams took his medical course at the University of Edinburgh, where he graduated with the degrees of Bachelor of Medicine and Master of Surgery in 1867; he also studied at St. Bartholomew's Hospital and qualified as M.R C S. Eng. and L S.A. He was a justice of the peace for the county of Denbighshire and took a keen interest in his *magisterial work*.

In 1876 he was elected honorary surgeon to the Wrexham Infirmary, a post which he held until 1881. *During* this period he gave his time, experience, skill, and encouragement to the suffering poor under his care, and there the kindly acts and unostentatious aid rendered to so many in a humbler sphere, although unrecorded, will not be forgotten. When a vacancy occurred later on the staff of that institution be diluted with water to the same concentration as normal blood serum. Distilled water is not suitable as a diluent, as it sometimes causes pain. It is better to dilute the sea-water with natural potable water in the proportion of 2 parts to 5. In conclusion, M. Carles points out that this method of treatment is not invariably suitable and that it rests with clinical experience to indicate the cases in which it may advantageously be employed.

LORD ROBERTS'S TROPHY FOR BRITISH (IMPERIAL) SCHOOLBOYS.

WITH the object of encouraging rifle shooting among boys under the age of 16—Government grants are only available for boys over this age—the committee of "Lord Roberts' Boys Association," 42, Sun-street, London, E.C., has issued a series of regulations under which the "Roberts Trophy" will be competed for by teams of primary schoolboys. The trophy will be given annually to the winning team of British (Imperial) schoolboys who are not over 16 years of age on July 1st in the year of the match. A bronze medal will be given to each member of the winning team, and a silver medal (the C. B. Fry medal) to the captain of the team. The first match will take place during the present year.

PRACTICAL HINTS ON MATERNITY NURSING, AND A "SPECIALIST."

THERE seems no end to the little books which are published on maternity nursing, and we have received another by "A Certificated and Experienced Nurse," published by the Scientific Press at the price of 6*d*. The information in this book is mostly trustworthy, but *although its author is undoubtedly well meaning she should* not write as follows. "*Unfortunately, few doctors seem to* understand the operation [circumcision] and make a long job of it, snipping the flesh away in places. ...... A neater and better effect is gained when circumcision is performed by one who knows how to do it," supplemented by a footnote—"Rev. A. Tertis, 'Specialist' in Circumcision, 33, Listria Park, Stoke Newington, N." We do not think that she should recommend the nurse to snip the mucous membrane in "tongue-tie" and we do not like her method of making a linseed poultice, but we take it that when she says "Each eye [of the baby] must be washed with a separate piece of rag and thrown away" she does not mean it. Otherwise the book is, as we have said, mostly trustworthy, and the list of "requisites" *for the mother, nurse, and baby is good.*

THE WINES OF WALLINGTON.

To the Editor of THE LANCET.

SIR,—In *Macmillan's Magazine* for January, 1880, the late Dr. (afterwards Sir) Benjamin Ward Richardson relates how on the First of April in the preceding year he had received an intimation by letter of a bequest which had been made to him by the late Sir Walter Trevelyan, Bart., of Wallington in Northumberland—a bequest which he considered of so remarkable a character that he could not rid his mind of a suspicion as to its genuineness, especially when he remembered that the intelligence regarding the benefaction had lighted upon him on All Fools Day. The letter acquainted him that the late Sir Walter Trevelyan (*a pronounced total abstainer like himself*) had left to him the wines in the *cellars of Wallington "to be applied to scientific* purposes." The wines, Dr. Richardson states, turned out many of them to be of great age as well as of rare vintage, the labels upon them dating as far back as 1752, but the chief difficulty with regard to them appeared to him to be how to apply them "to scientific purposes."

A perhaps pardonable spirit of inquisitiveness which a recent perusal of the *Macmillan* article has aroused prompts me to ask through THE LANCET, with your permission, whether any practicable scheme was ever devised *for* carrying into effect the beneficent desire of the testator in the application of the bequest "to scientific purposes," and if so what was its nature?

I am, Sir, yours faithfully,
W. R.

Dec. 26th, 1907.

THE MORPHINE HABIT IN RANGOON.

THE Superintendent of Excise at Rangoon, writing on the prevalence of the morphine habit in that city, says the present belief is that persons who habitually practise hypodermic injections to excess only live *for* a few years. The Superintendent of Excise and his assistant visited in June, 1900, a morphine den in Eighteenth Street and took the names and addresses of 30 persons present. Most of them were personally known to the assistant superintendent. On making inquiries in March, 1907, it was found and verified that all those 30 persons were dead. Some five had died from plague and the remainder from various other causes. This is probably an extreme instance, but it is evident that the habit is physically degrading as it is morally. At the suggestion of the Collector at Rangoon the Government *of* Burma has now ordered a leaflet describing the fatal effects of the *drug to be printed* and circulated in quarters where the morphine habit is known to hold sway.

MILK AND MANGLING.

SANITARY authorities are realising more than ever the importance of keeping a watchful eye upon purveyors of milk. Prosecutions are becoming more frequent and they should be the means of not only serving as a warning to milk-sellers but of drawing public attention to some of the conditions to which milk is subjected before it is retailed in small quantities. Two notices, "Mangling done here" and "Milk sold here," recently appeared in a window at a private house in Brighton and a visit by sanitary officers showed th in a small scullery were a mangle and a quantity of milk in a cha Offensive smells in the house and in the yard in the rear wa caused by their general dirtiness and were aggravated by the fa that greyhounds roamed about the place, the milkman being breeder of those animals. The sequel to the visit of the officers w the appearance of the milkman before the borough magistrates o Dec. 18th. He was summoned for failing to take reasonable an proper precautions in connexion with the storage and distribution o *milk and otherwise to* prevent the exposure of *milk on his* premis to any contamination. But the seriousness of the offence seems hardl to have been realised by the magistrates who only inflicted a fine o 40s. and costs, and this notwithstanding that defendant had bee warned about the condition of the premises 12 months before. I their decision the magistrates may have been actuated by the fa that it was the first prosecution of the kind in Brighton, althoug the regulation under which process was taken was one of a set mad as far back as the year 1900 by the corporation under the Dairi Cowsheds, and Milkshops Order of 1885.

◆

Concerned should notify the Registrar at 299, Oxford-street, Londo W., of the omission of his name and state exactly *how it* occurred His name will then be restored by a formal process at the next meeting of the General Medical Council on payment of a fee.

Veritas.—Abuse might arise out of advertisements similar to the one t which our correspondent calls our attention. But in the particula case we feel sure he need have no apprehension as *to* the aims of th lecturer or the value to the community *of his words.*

Button.—We must beg our correspondent to read the letters which hav so recently appeared in our columns, when he will find that all wh he says—we agree with most *of it*—has been said before.

ERRATUM.—In THE LANCET, of Dec. 21st, 1907, p. 1756, in a Note of a Case of Bone Abscess caused by an "Intermediate" Bacillus allied t Bacillus *Paratyphosus*, the sentence beginning "As the typhoid bacillus coagulates milk" should read "As the typhoid bacillus does not coagulate milk and renders glucose acid without the formation o gas the organism in question is generally classed as paratyphoid," &c.

COMMUNICATIONS not noticed in our present issue will receive attentio in our next.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (6th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (3 P.M.), St. Mark's (2.30 P.M.).

TUESDAY (7th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (2 P.M., Ophthalmic, 2.15 P.M.), Tottenham (2.30 P.M.).

WEDNESDAY (8th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Royal Orthopædic (3 P.M.), Children, Gt. *Ormond-street (9.30 A.M., Dental, 2 P.M.), Tottenham* (Ophthalmic, 2.30). P.M.

THURSDAY (9th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), *King's College (2 P.M.)*, Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Ormond-street (2.30 P.M.), Tottenham (Gynæcological, 2.30 P.M.).

FRIDAY (10th).—*London (2 P.M.), St. Bartholomew's* (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.).

SATURDAY (11th).—Royal Free (9 A.M.), London (2 P.M.), *Middlesex* (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), *St Mary's* (10 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), Wille, M.B., Ch.B., M.D., D.P.H.; T. F. Macdonald, M.B., C.M., M.R.C.V.S.; R. FitzHerbert Johnston, M.B., Ch.B.; and W. S. Snell, L.R.C.P., L.R.C.S. (Colonial Service).

* With distinction.

Donations and Bequests.—Under the will of Mr. Isaac Coley of Peckham, S.E., Guy's Hospital, St. Thomas's Hospital, University College Hospital, and the Lying-in-Hospital will each benefit by a sum of about £3000.

Medical Magistrates.—The Lord Chancellor has, on the recommendation of the Duke of Fife, the Lord Lieutenant of the county, added the name of Dr. R. J. Collie to the commission of the peace *for the county of London.*—Dr. Henry Willson of Weybridge has been placed upon the commission of the peace for the county of Surrey.

Presentation to a Medical Practitioner.—Mr. J. W. Smith, M.R.C.S. Eng., L.S.A., was on Dec. 25th last presented with a motor-car with accessories and motor-house by the inhabitants of Weaverham, Acton, Delamere, Cuddington, Norley, and surrounding districts in recognition of 40 years' professional services and 18 years' service as a Cheshire county councillor.

Tragic Death of a Medical Man.—Dr. George John Sealy of Weybridge, Surrey, lost his life on Dec. 24th last in a tragic manner. He was riding on horseback with his groom along the towpath towards Chertsey. Owing to the floods the path was quite unsafe and near Chertsey Bridge Dr. Sealy's horse, which was leading, plunged and slipped, with the result that both horse and rider were precipitated into the river. The horse managed to get out again but *nothing* could be seen of Dr. Sealy. The groom dismounted and tried to render assistance, as did also the driver of a van who witnessed the accident but neither could render any help to rescue the unfortunate medical man. Dr. Sealy became M.R.C.S. Eng. and L.S.A. in 1861 and M.D. St. Andrews in 1862 and worked in conjunction with Dr. R. D. R. Crofton-Atkins of Weybridge.

The Children's Sanatorium (Holt, Norfolk).—A first report, with accounts from March, 1904, to Dec. 31st, 1906, with a list of subscribers, has recently been issued. The sanatorium is established for the treatment of children, few sanatoriums taking children under the age of 16 years. The age of admission for girls is from two to 16 years and for boys (until permanent buildings are erected) from two to seven years. Cases must be in the early stage of pulmonary tuberculosis. Payment for cases depends on the condition of the maintenance fund. A limited number of cases are received at 7*s.* 6*d.* per week, other cases at 15*s.* per week, and other cases from unions or other local authorities are received by special arrangement. The length of stay depends upon the report of the visiting medical officer (Dr. J. B. Gillam of Holt) and upon the continuance of the payment, if any. On August 1st, 1906, the first batch of children arrived at Holt, "and up to the present time" (presumably the end of October, 1907) some 21 cases have been received. From the accounts we gather that £220 have been spent on the maintenance of cases, and that of the 21 cases so far taken 15 have paid 7*s.* 6*d.* a week, five have paid 15*s.* a week, and one has been taken free. The income annually required to maintain always 15 cases (a full occupation of the accommodation), if taken quite free, would amount to £850, or if the same number of children were to pay 7*s.* 6*d.* per week each, the sum necessary would be £550 per annum. The committee, however, appeals for an annual subscription of £700 in order that about half the cases may be taken without payment and half at 7*s.* 6*d.* per week. It also appeals for donations to the building fund. Dr. F. W. Burton-Fanning of Norwich, who is the honorary consulting physician, states that the Children's Sanatorium has acquired an ideal site at Holt and he trusts that it will be supported in its endeavours to supply a pressing want. Donations for the building fund, or donations or annual subscriptions for the maintenance of cases fund, will be gratefully received by the honorary secretary of the sanatorium (Mr. T. H. Wyatt, M.V.O.), at 68, Denison House, Vauxhall Bridge-road, London, S.W. The bankers are Messrs. Hoare and Co., London. The Rev. E. C. Bedford is the chairman of the committee and the treasurer is Mr. Alfred Hoare. As soon as the money is forthcoming 50 patients can be dealt with. Holt (near Cromer) should be of interest to Cambridge graduates on account of its connexion with Sir Thomas Gresham, "the Royal Merchant," who went to Caius College, Cambridge, and who, it is recorded, was called by Caius "Doctissimus mercator." Some authorities say he was born at Holt, but more maintain that London was his birthplace. However, he founded a school at Holt.

Derbyshire Women's Hospital.—The new buildings which form the extension of the Derbyshire Women's Hospital, Derby, were opened on Dec. 12th, 1907, by Lady Fitzherbert. The new buildings comprise an out-patient department, with waiting-room for 50 people, consulting and retiring rooms, and a dispensary; a ward containing seven beds and two smaller wards for such cases as are being treated apart; additional accommodation for the nursing and domestic staff; and a laboratory and workroom. The estimated cost of the additions to the hospital is about £2000. The hospital was founded in 1891, during which year 34 patients were treated. In 1906 the in-patients numbered 136 and the out-patients 1284.

Livingstone College.—Satisfactory progress in the work of this college is shown by the report for the year 1906–07, which was adopted at the annual general meeting of members held at the college, Leyton, London, E., on Dec. 10th, 1907. The deficiency of £522 at the commencement of the financial year has been reduced to one of £404. 32 students entered for the whole or part of the complete session of nine months, representing 15 different missionary societies, some of these coming from Germany, Switzerland, Sweden, Finland, and South Africa. The report points out that missionaries abroad are often responsible for the education of the young in the districts in which they are placed, and that they may be the means of giving instruction in hygiene, which may be of the utmost importance to the people of the country. Malaria, plague, and sleeping sickness are all of them, to a considerable extent, preventable diseases, and Livingstone College students may do much to combat their ravages.

Leprosy in India.—At Sabathu, where there is a large leper asylum for natives, a small cottage was set apart some time ago by Dr. Carleton, the American missionary in charge, for two European young women who had contracted the disease, and recently the number of inmates has been increased to five by the admission of two boys and a middle-aged man, all three with white skins. The price of grain food in India is at present very high, and we learn from the *Times of India* that mainly owing to this cause the bank account of the Mission to Lepers, of which Mr. Wellesley C. Bailey is superintendent, is now overdrawn to the extent of £1000. In Purulia, where there are 700 lepers in the asylum, the food is being bought at what once were considered famine rates, and at the Allahabad asylum the difference between former and present cost comes to Rs. 150 a month. Similarly depressing accounts are furnished by the numerous asylums in other parts of India which are dependent on the Mission. It is proposed to hold a conference next February at Purulia and delegates from Bengal, the United Provinces, the Central Provinces, and Central India are expected to attend.

The Weymouth and District Medical Club.—This club has recently been started on what is believed to be original lines. All resident medical men, active or retired, are eligible for membership, whilst Service men are invited to attend, as honorary members, the ordinary meetings of the club. The objects of the club are stated in its rules to be "the promotion of social intercourse and mutual support in any difficulties which may arise from time to time affecting the profession or individual members." The former object is attained by engaging a room in a central hotel, the Gloucester, in which the members may meet without any formality on one evening of each month in the winter, whilst provision is made for the latter by putting it into the power of any two members to bring any matter to the consideration of an early meeting of the committee, which consists of all the resident medical men in active practice. No permanent chairman or president is appointed but a new departure is made by a rule which places in the chair at any meeting of the club that member present who has been longest in actual practice in the district. An inauguration dinner, which was held at the Gloucester Hotel on Dec. 17th, 1907, was a great success and was attended by nearly every medical man in the place, the navy being well represented. The rule placing in the chair the senior

Communications, Letters, &c., have been received from—

A.—Monsieur J. Astier, Asnières; Messrs. C. Ash, Sons, and Co., Lond.; Aberystwyth Infirmary, Secretary of; Anglo-American Pharmaceutical Co., Lond., Manager of; Mr. A. Anderson, Northampton; Dr. Izett Anderson, Lond.

Ward, Richmond; Dr. W. H. Willcox, Lond.

CARDIFF INFIRMARY, GENERAL HOSPITAL.—House Physician for six months. Salary £30, with board, residence, and laundry.

CHARING CROSS HOSPITAL.—Assistant Physician.

CHESTERFIELD AND NORTH DERBYSHIRE HOSPITAL.—Senior House Surgeon. Salary £120 per year, with board, apartments, and laundress.

DEVONPORT, ROYAL ALBERT HOSPITAL.—Resident Medical Officer, unmarried. Salary £100 per annum, with apartments, board, &c.

ENNISKILLEN, FERMANAGH COUNTY HOSPITAL.—House Surgeon. Salary £52 per annum.

HARTLEPOOLS HOSPITAL.—House Surgeon. Salary £100 per annum, with board, washing, and lodging.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton. —Resident House Physicians for six months. Salary £25.

HULL, ROYAL INFIRMARY.—Two Casualty House Surgeons. Salary at rate of £60 per annum for six months and of £80 for 12 months, with board and lodging.

LEEDS PUBLIC DISPENSARY.—One Pathologist, Five Dental Surgeons, and Four Assistant Dental Surgeons, all honorary.

LIVERPOOL INFECTIOUS DISEASES HOSPITAL.—Assistant Resident Medical Officer, unmarried. Salary £120 per annum, with board, washing, and lodging.

LONDON FEVER HOSPITAL, Liverpool-road, N.—Resident Medical Officer. Salary £200 per annum, with board and residence.

LONDON LOCK HOSPITAL, Soho.—House Surgeon to the Male Hospital. Salary £80 per annum, with board, lodging and washing.

NATIONAL HOSPITAL FOR THE RELIEF AND CURE OF THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury.—Assistant Physician for Out-patients.

NORTHAMPTON GENERAL HOSPITAL.—Assistant House Surgeon, unmarried. Salary £50 per annum, with apartments, board, washing, and attendance.

NORTH EASTERN HOSPITAL FOR CHILDREN, Hackney-road, Bethnal Green, E.—Assistant Physician.

PADDINGTON GREEN CHILDREN'S HOSPITAL, London, W.—Honorary Anæsthetist, also Honorary Radiographer.

PORTSMOUTH, ROYAL PORTSMOUTH HOSPITAL.—Assistant House Surgeon for six months. Salary at rate of £50 per annum, with board, &c.

SAINT GEORGE'S UNION INFIRMARY, Fulham-road, London, S.W.—Second Assistant Medical Officer. Salary £120 per annum, with board, residence, and washing.

ST. MARY'S HOSPITAL MEDICAL SCHOOL, Paddington, W.—Junior Demonstrator of Physiology. Salary at rate of £100 per annum.

SHEFFIELD, UNIVERSITY OF.—Demonstrator in Anatomy. Salary £150 per annum

SOMERSET COUNTY COUNCIL.—Chief Medical Inspector of Schools. Salary £500 per annum, with necessary out-of-pocket expenses.

SURREY DISPENSARY, Southwark, S.E.—Physician.

SWANSEA COUNTY BOROUGH.—Medical Officer of Health. Salary £500 per annum.

TAUNTON UNION, NORTH CURRY DISTRICT.—Medical Officer. Salary £75 per annum and fees.

UNIVERSITY COLLEGE HOSPITAL, Gower-street, W.C.—Resident Medical Officer.

WADSLEY, NEAR SHEFFIELD, WEST RIDING ASYLUM.—Fifth Assistant Medical Officer. Salary £140 per annum, rising to £160, with board, &c.

WARRINGTON UNION WORKHOUSE.—Resident Medical Officer. Salary £150 per annum and fees, with apartments, rations, &c.

WEST-END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM, PARALYSIS, AND EPILEPSY, 73, Welbeck-street, London, W.—Physician to Out-patients.

WEST HAM HOSPITAL, Stratford, E.—Junior House Surgeon for six months. Salary at rate of £75 per annum, with board, residence, &c.

WREXHAM INFIRMARY.—Resident Medical Officer. Salary £80 per annum, with board, lodging, and washing.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Dronfield, in the county of Derby; and at Stratford, in the county of Essex.

Births, Marriages, and Deaths.

BIRTHS.

SIBLEY.—On Dec. 27th, 1907, at The Mansions, Duke-street, Grosvenor-square, W., the wife of W. Knowsley Sibley, M.A., M.D., of a daughter.

WORTHINGTON.—On Dec. 29th, 1907, at The Sycamores, Birchington, Thanet, the wife of H. E. Worthington, M.R.C.S., L.R.C.P., of a daughter.

MARRIAGES

GREENWOOD PENNY—PHILLIPS.—On Nov. 14th, 1907, at St. James's, Exeter, by the Rev. P. Williams, the Rev. W. David and the Rev. R. Reid, Sydney Greenwood Penny, M.R.C.S., L.R.C.P., of Penmeneth, Marazion, Cornwall, younger son of the late Robert Greenwood Penny of Nethergrove, Chulmleigh, N. Devon, to Gwenllian Helen Leigh, younger daughter of the late Rev. James Phillips of Exeter.

JONES—EVANS.—On the 1st inst., at Aberayron, Edmund Benjamin Jones, F.R.C.S. Eng., of "Chatsworth," North End-road, Golder's Green, N.W., to Ina Margaret, second daughter of the late Llewelyn Evans, of Pantclynhir, New Quay, Cardiganshire.

DEATH

GARROD.—On Dec. 28th, 1907, at Harley-street, Cavendish-square, W., Sir Alfred B. Garrod, M.D., F.R.C.P., F.R.S., Physician Extraordinary to her late Majesty Queen Victoria, in his 89th year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE PUBLIC TELEPHONE CALL OFFICE AS A FACTOR IN THE SPREAD OF DISEASE.

IN our issue of July 27th, 1907, p. 240, we directed attention to the unventilated condition of the public telephone call offices and to the possible risk of contracting infectious disease while using them. In the construction of these call offices it is essential that external noises should be excluded as much as possible in order that the person who is inside may be able more easily to hear what is said to him from the distant station. Hence the difficulty of ventilation. The substance of our article was reproduced in *Didaskalia*, a periodical published in Frankfort, and Mr. Richard Goll of that city has consequently written to us that he is the patentee of a system of ventilation which has been successfully applied to telephone call offices. According to the description which we have received it is an arrangement of tubes or conduits (*eine Anordnung von Leitungen*) the action of which is noiseless and automatic, depending only on natural or accidental differences of pressure (*Luftdruckunterschiede*). Particular attention is called to the fact that at the Hotel Marquardt in Stuttgart there are four telephone call offices (*Telephonzellen*) for the use of visitors, and the ventilation of these by Mr. Goll's system has given satisfaction.

HUMOUR.

IT is a good sign when human beings can appreciate humour. Not so very long ago a play of fancy was supposed to be incompatible with science. Science was regarded as a sober, solemn affair on no account to be treated lightly. Geniuses were serious creatures of whom but a small minority could understand a *jock* and that with *deefficulty*. To effect an entrance for a witticism into their surcharged sensoriums surgical operations were a preliminary essential. We have been led to make these frivolous remarks by Captain J. Crawford Kennedy, R.A.M.C., who has successfully extracted "A Little Humour from the Malta Commission" for publication in the December number of the journal of his corps. At the risk of some of the allusions proving caviare to the general unfamiliar with the internal economy of line regiments, we venture to reproduce the extract from an adjutant's letter with which Captain Kennedy closes his article.

> DEAR KENNEDY,—P. has passed your note on to me, and all our men are now running about with butterfly nets, or trying to tempt the wily mosquito with lumps of raw meat, and I've indented for a small size of mouse-trap, but am doubtful if the Government will supply the necessary bait. Up to the present the bag is one, and he struggled so when our regimental police were effecting his capture that he had to be hit hard on the head and I'm afraid is almost unrecognisable. PS.—Another capture just reported. We've put him in the guard room till your boxes arrive. He has been biting —— and was consequently drunk and his capture was easy. Ought mosquitoes (when drunk) to have their boots removed?

THE MEDICINAL EMPLOYMENT OF SEA-WATER.

IN a recent number of the *Répertoire de Pharmacie* M. P. Carles gives an interesting account of the use of sea-water in medicine. In addition to common salt sea-water contains many important mineral substances, the total solid matter amounting to 3·2 to 3·8 per cent. Some of these substances are present only to an infinitesimal extent, but in biology the value of a substance is not necessarily dependent upon its actual size or quantity. It has been shown that various marine plants have the power of extracting from sea-water minute quantities of compounds of iodine, bromine, arsenic, boron, manganese, lithium, fluorine, rubidium, cæsium, and other elements. Hence it was not unreasonable to suppose that the higher animals might derive benefit from the assimilation of even minute traces of these physiologically active substances. The employment of sea-water as a remedial agent dates back to the time of Hippocrates, and modern physiological investigations have led to its reintroduction into medicine. Thus it has been shown that if a portion of the blood serum of a dog be replaced by an artificial serum the most suitable serum for the purpose is sea-water, isotonic with the natural serum. Sea-water has been given by the mouth and by injection with good results in cases of dyspepsia, loss of appetite, and tuberculosis. In general the appetite was improved and strength was rapidly regained. In order to obtain the best and most immediate results it is necessary to observe certain precautions. The sea-water must be natural as it is impossible to imitate so complex a liquid. Indeed, it has been proved that sea-salt, when re-dissolved in distilled water, lacks some of the properties of natural sea-water, exerting a toxic action upon a dog when injected subcutaneously. It must be freshly collected, as it loses carbon dioxide on standing, with precipitation of some of its salts. It should be taken from the open sea remote from rivers and other sources of pollution. It should be sterilised by filtration, as heat dissociates the bicarbonates and destroys the natural equilibrium of the liquid. When required for subcutaneous injection it should the surrounding counties, the death-rate from tuberculosis is so high? Secondly, the census returns for the last three decades indicate an extraordinary influx of lives into Belfast between the ages of 15 and 35 years (females showing an abnormally high proportion). These are good lives, and yet we have a high consumption rate. Thirdly, notwithstanding the fact that emigration has produced a curious age distribution of population in Ireland (persons aged 60 years and upwards are equal to 14·2 per cent. of the total population of Ireland, as compared with 10·4 per cent. of the total population of England and as compared with 10·9 of the total population of Scotland) it is a remarkable fact that the birth-rate, corrected for the number of women at child-bearing ages and for the number of married women, has actually increased in Ireland, while it has decreased in England and Scotland, a fact which indicates that fertility and vitality have not decreased in Ireland. Fourthly, if the cause of the high tuberculosis death-rate in Ireland be the physical decadence of the people in Ireland, what about the condition of those who leave our shores for America? Well, it is stated that in the United States (and figures have been given) the phthisis death-rate for the Irish is higher than for other nationalities. According to this view, if the occurrence of tuberculosis be taken as a test of a physically inferior people those who emigrate are no better than those who remain behind. Fifthly, Belfast is in that part of Ireland which has probably suffered least from emigration and where prosperity is, from a commercial point of view, the greatest, and yet its death-rate from tuberculosis is very high. Sixthly, in a recent examination of recruits the smallest number of rejections were among the Irish. Seventhly, as pointed out by Dr. A. Newsholme, in the past it was the small farmers, the cottiers, and the labourers who emigrated in the largest numbers and these, owing to their extreme poverty, must have been among the least fit, while on the other hand those remaining are the offspring of people more favourably situated and who have been living under progressively better conditions than their predecessors in the past and who accordingly should be more vigorous.

4. *The susceptibility of Irish people to tuberculosis.*—It has been stated that there was in the Irish (some said the Celtic, including the Scotch Highlander) race a soil upon which the tubercle bacillus grew with extraordinary facility, and American statistics have been quoted to support this view, and it has also been laid down that Ireland by that reason was severely handicapped in the race with other countries to stamp out tuberculosis. I deny altogether that Irishmen, as a race, are specially prone to consumption. Why was it that according to the Registrar-General's return Ireland in 1864, when there were far more Celts in the country, had a lower death-rate from tuberculosis than either England or Scotland? Again, it was curious that of the smaller urban towns in Ireland the one with the highest phthisis death-rate was Newtownards, situated in the most Scottish county in Ireland, Down, where, at the time of the Ulster plantation, the people came not from the Highlands, the home of the Scotch Celts, but from the Lowlands. The people of Ireland are unfortunately suffering from tuberculosis not because they are Irish or Celts but because, as I shall show later, through want of education, they have not been taught in the past how to grapple with the white plague, and our emigrants in America suffer largely for the same reason, and also because they keep so much together and are influenced by their environment (that is, the conditions under which they live). Further, I do not accept the view that a high consumption death-rate is a sign of physical inferiority any more than I do that the existence of typhus fever in Ireland in the past was to be regarded in the same way. In both cases their prevalence was, and is, due to want of care being taken to stamp them out.

5. *Poverty and social position as a cause of tuberculosis.*—The fact that comparing the mortality in the four classes the rate was, from tuberculosis, 0·63 in the professional or independent class, 2·79 in the middle class, 3·54 amongst the artisan and petty shopkeepers, and 4·12 in the general service class, shows that amongst those better housed, clothed, and fed the mortality is much less than among those who have not the same advantages as regards these factors, and whose occupation is more exposed, severe, and laborious. But this explanation, it must be admitted, applies to almost every disease (infectious or not) as well as to tuberculosis. Yet, on the other hand, we must not forget that Ireland has during the past quarter of a century shared with England in increased cheapness of food and of living; wages have increased, and the savings bank returns show that while in 1870 the lodgments were £2,700,000 they had increased to £6,970,000 in 1894.

6. *Food and drink.*—There is ground for believing that the increased use of tea and white household bread instead of the old porridge and buttermilk and the excessive use of alcohol have lowered the resistance of the people to the tubercle bacillus. The food which is of greatest importance in reference to tuberculosis is milk, because it is now practically agreed that the bacillus of tuberculosis is the same in the cow and in man and that the disease is intercommunicable, and in the second interim report of the Royal Commission appointed to inquire into the relation of human and animal tuberculosis, Part I., Report, 1907, pp. 36 and 37, the Commissioners in their conclusion make the following weighty deliverance:—

> A very considerable amount of disease and loss of life, especially among the young, must be attributed to the consumption of cow's milk containing tubercle bacilli. The presence of tubercle bacilli in cow's milk can be detected, though with some difficulty, if proper means be adopted, and such milk ought never to be used as food. There is far less difficulty in recognising clinically that a cow is distinctly suffering from tuberculosis, in which case she may be yielding tuberculous milk. The milk coming from such a cow ought not to form part of human food and ought not to be used as food at all.
>
> Our results clearly point to the necessity of measures more stringent than those at present enforced being taken to prevent the sale or the consumption of such milk.

I am in a position to say, from a communication which I have received from one of these Royal Commissioners, that "the German commission has ultimately come to much the same conclusion as we have, and the Americans have fallen into line." In Ireland it has been estimated that probably at least 30 per cent. of the milch cows are afflicted with tuberculosis. Now, in the children's hospitals in Belfast—and the same is true of similar institutions in England and Scotland—about from 20 to 30 per cent. of all the children treated suffer from various forms of tuberculosis (bones, joints, glands, abdominal and cerebral types). As a rule these hospitals do not admit children over 12 years of age and it is curious that the pulmonary forms of tuberculosis are rare, showing that the disease is not in them so often acquired by inhalation as in adults—while, on the other hand, the ravages of the disease in children who require surgical treatment far outnumber what are called the medical forms of tuberculosis. One is driven to the conclusion that the disease is acquired in children largely by ingestion through swallowing tuberculous milk.

7. *Industries.*—According to some it is the influence of industries—especially in towns—which causes the high tuberculosis death-rate. Now, it is curious that in Dublin they have little or no textile industries as in Belfast, and yet the Dublin phthisis death-rate is the higher of the two cities. Then in Bolton, Manchester, Oldham, and other towns where there are cotton and other industries the death-rate from phthisis has fallen, while it has not done so in Ireland. Further, in Great Britain, much of the reduction of phthisis had occurred before systematic action had been well begun for the suppression of dust in factories. Year by year the conditions in the mills regarded as inimical to health—dust, damp, high temperature, and imperfect ventilation—have improved, and in 1904 Commander H. P. Smyth, in his report upon flax mills, says: "I cannot speak too highly of the efforts that have been made by many [manufacturers]. They have spent time, thought, and large sums of money, going far beyond any legal requirements that have yet been made." I am firmly convinced that the influence of industries—especially the textile ones—as a contributory cause of tuberculosis in Ireland has been overstated. Legally, the owners of mills are obliged to reduce as much as possible anything in their works inimical to health and taking Belfast, the great industrial centre of Ireland, as an example, supposing the death-rate was proved to be higher among the workers in mills and in factories in that city than among the rest of the population, still that excess would raise the total death-rate only by a twelfth part, because at the present time the numbers of these workers are about 25,000 females and 5000 males; therefore, if the mill and factory death-rate were 23 per 1000, whilst the total death-rate was 20, to eliminate the 30,000 mill-workers would make the death-rate 19·75, instead of 20 per 1000.

8. *Want of sanitary reform in Ireland.*—There can be no question that in the past we have not made the same progress as has been done in England and Scotland in the sanitary measures taken to improve the dwellings of the people all over the country, and in both England and

JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, icester-square, W.C.

Thursday.—6 P.M., Lecture:—Dr. M. Dockrell: Bullous and Vesicular Eruptions: I., Urticaria; II., Pemphigus; III., Pompholyx; IV., Varicella.

EDITORIAL NOTICES.

It is most important that communications relating to the itorial business of The Lancet should be addressed clusively "To the Editor," and not in any case to any ntleman who may be supposed to be connected with the itorial staff. It is urgently necessary that attention be en to this notice.

is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

ctures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

tters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

e cannot prescribe or recommend practitioners.

ocal papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

etters relating to the publication, sale and advertising departments of The Lancet *should be addressed "To the Manager."*

e cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

The Index and Title-page to Vol. II. of 1907, which was ompleted with the issue of Dec. 28th, are given in this umber of T [illegible]

VOLUMES AND CASES.

Volumes for the second half of the year 1907 will be ready shortly. Bound in cloth, gilt lettered, price 18*s*., carriage extra.

Cases for binding the half year's numbers are now ready. Cloth, gilt lettered, price 2*s*., by post 2*s*. 3*d*.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

Will Subscribers please note that only those subscriptions which are sent direct to the Proprietors of The Lancet at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach The Lancet Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to The Lancet Offices.

Subscribers, by sending their subscriptions direct to The Lancet Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The Colonial and Foreign Edition (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from The Lancet Offices or from Agents, are:—

For the United Kingdom.		To the Colonies and Abroad.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. Charles Good, The Lancet Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

Subscribers abroad are particularly requested to note the rates of subscriptions given above. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of The Lancet necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of The Lancet have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra *postage*.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—The Manager, The Lancet Offices, 423, Strand, London, England.

METEOROLOGICAL READINGS.

During the week marked copies of the following newspapers have been received:—*Coventry Herald and Free Press, Reading Mercury and Oxford Gazette, Nottingham Evening News, North Mail (Newcastle), South Wales Daily News, Sanitary Record, Birmingham Despatch, Standard, Yorkshire Daily Post, Newcastle Chronicle, Preston Guardian, Dublin Evening Telegraph, Liverpool Courier, Pall Mall Gazette, Hereford Times, Yorkshire Daily Observer, Nottingham Press, &c.*

(1845–48) the restrictions as to the giving of outdoor relief were for the time relaxed, and after the famine the rigid rules as to outdoor relief were reimposed; but, notwithstanding, outdoor medical relief gradually became more general, and from 1880 onwards the general policy of the Poor-law authorities was completely inverted, until in the year 1903–04 it is really astounding to record that the proportion of new cases of sickness attended, either at dispensaries or in their own homes, formed nearly one-eighth of the total population of Ireland. When I speak of outdoor relief in Ireland I mean, of course, medical relief given in the forms of medical attendance, advice, and medicine, either at the dispensaries or at the homes of the patients, and if we have to lament that pauperism in this sense has not declined in Ireland, it is clear that it is due to statistical and administrative causes. In Great Britain, as pointed out by Dr. Newsholme, the regulation has been generally enforced that in order that a sick or disabled husband among the poor may receive relief to which his destitution entitles him he must enter the infirmary. A sick wife, however, is not entitled to parochial relief so long as her husband is in receipt of wages sufficient to support her. This is the reason why a much larger proportion of male than of female consumptives are treated in England in workhouse infirmaries.

In an extremely interesting recent paper by Dr. Newsholme, to which as well as to his other thoughtful writings I gladly acknowledge much indebtedness, he points out the remarkable fact that while typhus fever has diminished in Ireland, phthisis has contemporaneously increased, and asks this question, "Now, if improvement in general well-being of the population associated with better nutrition, diminished overcrowding, and improved houses has, as is commonly stated, been the main determining cause of the diminished mortality from typhus and phthisis in England and in Scotland, how has the equally striking diminution of typhus in Ireland been brought about and why has it not only been accompanied by any diminution in the death-rate from phthisis but by an actual increase in the death-rate from this disease?" It is plain that the reduction of typhus fever and the increase of phthisis in Ireland have both of them been associated with Poor-law administration. As Dr. Newsholme puts it, at first outdoor or domestic relief under the Irish Poor-law was very restricted, but in the process of time the Poor-law policy of Ireland was changed, medical and other forms of relief being freely given to people still living at home. During the last 25 years outdoor medical relief had been more largely given than indoor relief, especially when allowance is made for the fact that indoor relief includes the provision of a large portion of the general hospital accommodation of Ireland. Associated with this changing administration was the fact that residential conditions of relief were imposed, which tended to prevent the great vagrancy and mendicancy which had prevailed so much in Ireland. What would be the effect on typhus fever and phthisis of (1) the increasing immobilisation of the population in their own districts, and of (2) the increase in the proportion of sickness in the aggregate, and especially of phthisis, treated in the homes of the people? The readiness with which medical treatment, both at home and at the dispensary, could be obtained led to the greater portion of the lives of consumptive patients being spent at home. For typhus fever it was otherwise. Here was a disease which, unlike phthisis, was not infectious for several years but only for two or three weeks and which disabled immediately instead of after protracted ill-health. The objections of the people to the union hospital were easily overcome for this disease, but only rarely in the case of phthisis. Hence, Dr. Newsholme shows, the same measures which were successful for typhus fever led to an actual increase of phthisis. Typhus fever has been brought to the point of extinction by *its institutional treatment, acting in conjunction* with the removal of the motives for vagrancy. Phthisis has been rendered even more prevalent than formerly by increasing for this disease domestic at the expense of institutional treatment, and by thus continuing the enormous number of domestic foci of this disease which are implied by the home medical treatment of phthisis among the poor.

10. *Popular ignorance of the nature of tuberculosis.*—Lastly, want of knowledge on the part of the public of the nature of the disease, of the measures needed for its prevention, and of the precautions required to limit its spread is a factor of importance as explaining the great prevalence of tuberculosis in Ireland. Want of knowledge brings carelessness, indifference, and in the end even apathy.

Having tried, therefore, to show why tuberculosis is still so prevalent in Ireland, and remembering that it is an infectious disease due to a bacillus which may enter the body either through the pulmonary system by being inhaled, or by the alimentary tract by being swallowed, and occasionally through a skin wound, what steps should be taken to combat the disease in Ireland?

PRACTICAL SUGGESTIONS FOR THE PREVENTION AND TREATMENT OF TUBERCULOSIS IN IRELAND.

1. The starting point for dealing with all infectious diseases or pestilences is notification, and in my opinion this must be made compulsory in the case of tuberculosis all over the country. In no other way can we know where the disease exists or what stage it is in, and unless both these facts are ascertained how can any attempt be made to deal with it from a public health point of view? Nothing seems more incongruous than the prompt care that is properly taken to cut short an outbreak of small-pox, typhus fever, or spotted fever in Ireland, and the utter apathy displayed in dealing with an infectious disease like tuberculosis, whose victims are so immensely more numerous than *those of* all the other infectious maladies combined. Compulsory notification is the first and most essential step in the anti-tuberculosis campaign.

2. When by notification we know where the disease is, our next duty is to pursue in Ireland, as is being done in every country where the death-rate from tuberculosis has fallen, the institutional treatment of pulmonary phthisis, especially of those advanced cases which are so ill as to be unable to look after themselves, and who in the interest of the healthy members of the household, must be removed, just as cases of typhus fever are in Ireland and as advanced cases of leprosy are isolated in Norway. Separate wards could be arranged for these advanced "open" cases, which are more dangerous the nearer they come to the end, in the union hospitals, where they would be so much better attended and nursed than at home. As we know that pulmonary consumption is mainly spread by infection from a tuberculous patient, the placing of such a person in a hospital or an infirmary releases his household from its principal exposure to infection, but further by reducing anxiety and worry it indirectly improves the health of the family. In Ireland, if we are to stamp out the disease, the institutional (that is by hospital or infirmary) treatment of advanced cases of pulmonary consumption must be done on a scale not hitherto thought of, and such treatment must be made attractive. If it is absolutely necessary, then there should be fresh legislation declaring tuberculosis an infectious disease; but even without waiting for this the Irish Local Government Board might follow the example of the Local Government Board of Scotland which took the bold and independent course on *March 10th, 1906,* of issuing a circular (Public Health, No. 1, 1906) in which it was laid down that tuberculosis of the lungs or consumption was an infectious disease within the meaning of the Public Health Act, and that the sections of the Public Health Act applicable to other infectious diseases are equally applicable to pulmonary phthisis, and the obligation resting on the local authority to deal with and control infectious *disease* was made to extend to pulmonary phthisis.

The provisions of the Public Health Act as to removal of cases of *infectious disease to hospital* and as to the provision of hospitals are available for dealing with cases of pulmonary phthisis as with cases of other infectious diseases. These provisions, the circular points out, can be adapted in practice to any type of case—incipient cases, where the danger of infection to others, though for the time at a minimum, may suddenly become serious; intermediate cases, where the patients, still able to work, may, if uncontrolled, become dangerous; and advanced cases, where the patients, frequently unable to attend to themselves, may be a source of grave danger. With reference to the advanced cases, "the isolation of such dangerous cases," says *this* circular of the Scottish Local Government Board, "is a primary duty of the local authority." When a case of typhus fever, small-pox, or scarlet fever is sent into a union fever or other hospital in Ireland such a case must not be removed (being dangerous infectious diseases) whilst so suffering under a penalty of £5, and any person in charge of the case which is thus removed is liable to a similar fine of £5, yet at present an advanced case of pulmonary tuberculosis, the most dangerous of all forms of tuberculosis, and admittedly most infectious, *can*, *if* in a union or other hospital, be removed at any time, and can be taken home to spread disease by infection among the family.

An Address

ENTITLED

WHY IS TUBERCULOSIS SO COMMON IN IRELAND?

WITH SUGGESTIONS FOR ITS PREVENTION AND TREATMENT.

Delivered in Lurgan on Dec. 18th, 1907, in connexion with the Tuberculosis Exhibition,

BY SIR JOHN BYERS, M.A., M.D. (R.U.I.),

PROFESSOR OF MIDWIFERY AND DISEASES OF WOMEN AND CHILDREN, QUEEN'S COLLEGE, BELFAST.

APPALLING STATE OF IRELAND WITH REGARD TO TUBERCULOSIS.

MR. CHAIRMAN, LADIES AND GENTLEMEN,—That tuberculosis (that is, consumption in its various forms)—and the Tuberculosis Exhibition here demonstrates that almost every part of the body may be affected—is far too prevalent in Ireland is evident from the following facts, most of which are shown in the statistical charts on the walls of this room. 1. In the records of the various countries of the world Ireland stands fourth highest in its mortality from pulmonary tuberculosis, being only exceeded by Hungary, Austria, and Servia. 2. Comparing England, Scotland, and Ireland, it appears that while in 1864 Ireland stood lowest of the three, with a rate of 2·4 per 1000 living, the rate for England being 3·3 and that for Scotland 3·6, in 1905 and in 1906 Ireland was highest with a rate of 2·7, Scotland next with 2·1, and England lowest with a rate of 1·6. In 1879 the death-rate in England and Ireland from tuberculosis was about the same, and in 1885–86 it was the same in Scotland and Ireland. In Ireland in 1906 no less than 11,756, or 15·8 per cent., of the total deaths were due to tuberculosis—that is, more people died from this cause alone than from cancer and all the principal epidemic diseases (influenza, whooping-cough, typhoid fever, measles, diphtheria, and diarrhœa) added together. Further, the majority dying were in the prime of life (between 15 and 45 years of age) and for every death from tuberculosis there were at least ten persons suffering from various forms of that disease, many of whom have their wage-earning power diminished or altogether taken away. It is a terrible feature of the white plague in Ireland that the mortality is greatest in those ages which ought to form the very backbone of our people. 3. Further, since 1873 in England and Wales, and since 1870 in Scotland, the mortality from what is ordinarily called consumption—pulmonary phthisis—has been reduced by one-half among females and one-third among males, yet there is no such fall in Ireland. In 1906, again, more women than men died in Ireland from pulmonary or tuberculous phthisis.

The above facts show that the condition of Ireland as regards tuberculosis is simply appalling and demands the most careful consideration.

TUBERCULOSIS AN INFECTIOUS DISEASE.

As you are aware, tuberculosis is now regarded as an infectious disease, the immediate cause being the bacillus or rod-shaped vegetable organism discovered in 1882 by Koch, so microscopic in size that it has been computed that four hundred millions could be ranged close together on the surface of a penny postage-stamp. There are two avenues by which the cause of the disease enter the body—first, by inhalation of the germs directly by close contact with a person suffering from pulmonary phthisis (being disseminated in the act of coughing, shouting, &c., in the form of minute moist particles of spray), or indirectly, through dust containing the dread bacillus given off in the expectoration of a careless person ill of the disease; and secondly, by the ingestion of tuberculous meat and milk, but there can be no question that of the two (meat and milk) the latter (milk) is much the more important, because while meat is taken cooked (which destroys the bacilli) in small quantities by adults whose power of resistance, or immunity as it is scientifically termed, is increased, milk is taken in large quantities in a raw condition—often as their sole food—by children, with relatively diminished powers of resistance. The bacilli may also find an entrance by skin wounds, or they may be carried in with air in mouth inspiration, or by dirty objects placed in the mouth by children. When the bacilli reach a favourable place or nidus they multiply rapidly and by their presence and irritation they excite the surrounding tissues to increased growth which results in the formation of nodules called "tubercles." These in turn usually soften, and if in a lung are coughed up as the expectoration, if in a limb they form a discharge (abscess).

There are two factors in the causation of tuberculosis; first the bacilli, and secondly the predisposition or susceptibility of the individual; and certain conditions, to be mentioned later, might increase or diminish the infectivity of the bacilli, while on the other hand certain factors heighten or lessen the susceptibility of the individual. We are now in a position to attempt to answer the question, "Why is tuberculosis so common in Ireland?". I propose to-night to discuss some of the reasons that have been usually assigned.

CAUSES ASSIGNED FOR THE PREVALENCE OF TUBERCULOSIS IN IRELAND.

1. *The damp climate.*—We have been told that the prevalence of tuberculosis in Ireland is due to its damp atmosphere, the general humidity causing chest affections which tend to form a nidus for the tubercle bacillus. At the opening of the Tuberculosis Exhibition in Dublin Professor William Osler, in alluding to this view, denied it altogether, and pointed out Cornwall with a much damper atmosphere than in Ireland as being a place so free from the disease that consumptives were sent there. In comparing different towns I was much struck with the fact that while in Belfast the death-rate from phthisis was in 1906 2·77 per 1000, with a rainfall of 34·57 inches, in Glasgow with its humid atmosphere and higher rainfall (35·80 inches) the phthisis death-rate was only 1·5 per 1000. In Bolton with a moist climate and a rainfall of 42·43 inches the death-rate from phthisis has fallen to 1·11 per 1000 for 1906. In Cardiff (with a damp climate and with the ground water in many places near the surface in the gravel and with the lower part of the town near the docks, moors, &c., on a stiff marine clay, very retentive of moisture) the death-rate for 1906, with a big rainfall of 42·81 inches in this town (very much recovered from the sea as Belfast was) instead of being, as in Belfast, with a smaller rainfall of 34·57 inches, 2·77 per 1000, was only 1·20; and it has steadily fallen. In Manchester the climate is both damp and foggy, and the deprivation of light is greater than in any other English city (in spite of strenuous efforts to deal with smoky chimneys); yet, notwithstanding this, the phthisis death-rate has fallen to 1·82 in 1906. In Liverpool, a damp city, it is 1·82, and in London, with its fogs at times, the phthisis death-rate in 1906 was only 1·42. Again, if we go to Dublin, with a rainfall less than in Belfast (27·73 as compared with 34·57 inches in Belfast), the death-rate from consumption was 2·91 (that is, higher than in Belfast) for 1906. I cannot, therefore, admit that there is much in the dampness of the atmosphere as a cause of tuberculosis in Ireland.

2. *Dampness of the soil.*—The dampness of the soil has also been assigned as a cause. Now, it used to be thought that after places were thoroughly drained the phthisis-rate fell, and the experience of Salisbury and Ely were formerly quoted in support of this view; but it was forgotten that in another town, Chichester, that was not drained at all, the phthisis death-rate fell, probably owing to the larger proportion of phthisical patients who died in the workhouse in that town, while in Belfast the main-drainage scheme has had no effect in diminishing the phthisis death-rate. Whilst subsoil may be of some importance it is now recognised that other conditions are of much more potency in the problem of the causation of phthisis. It is a curious fact, as shown in the annual report of the Registrar-General for Ireland in 1904, that in reference to the seasonal mortality from tuberculosis the greatest number of deaths were registered in the June quarter.

3. *Emigration as a cause of tuberculosis.*—It is held by some that the long tide of emigration from Ireland has left behind a physically inferior population—a race of weaklings who propagate weaklings—all very susceptible to phthisis. I am aware that many hold this view, but there are serious scientific objections to it. First, Why is it that in a comparatively new town like Belfast, which—from its industries supplying employment—attracts the robust and strong from

years previously. From here it appears to have spread slowly and in an uncertain manner in an almost due easterly direction until it reached the coast. The line of its extension corresponds accurately with the chief trade route in this region and it is by reason of its following this course that the Chinese province to the north and India to the south with their teeming millions escaped infection at this time. It reached Pakhoi on the Tonquin Gulf in the year 1867, from which place, and also directly from Yunnan, it travelled to Canton which it reached in 1894; Hong-Kong which is in close proximity to and in intimate commercial relationship with, Canton became infected in the same year. Bombay was infected in 1896, a date which marks an important epoch in the history of the pandemic, for previously no extension inland on a large scale had taken place from any of the infected ports. How the disease was imported into Bombay is not exactly known. Plague cases and dead rats were first discovered in the vicinity of the docks accommodating cargo steamers from Hong-Kong. It commenced in a slow and insidious manner and it was some time before its real nature was recognised. The plague history of Bombay since 1896 has been marked by two features; first, the annual recrudescence of the disease in an epidemic form; and secondly, its extension inland, so that this city has acquired the character of being the great distributing centre from which the disease has spread nearly all over India. The rapidity and extent with which this has taken place have been further increased by the fact that perhaps now, for the first time in the history of the present pandemic, modern facilities of locomotion became available for its dissemination by land.

It was not until 1901 that the epidemic appeared to reach the Punjab, the most northerly province of India; in the spring of 1907 Peshawar, a city in the extreme north-west corner of India, was infected for the first time, and cases of the disease have recently been reported from Jellalabad and Kabul in Afghanistan. In addition the disease is slowly spreading westwards along other trade routes leading from India into Afghanistan; thus Dera Ismail Khan at the head of the Gomul trade route and Edwardesabad at the head of the Tochi valley have this year become infected. Further south, by another route, Seistan is already infected, so that the disease is showing a marked tendency to spread westwards by various channels of communication leading from India. It therefore appears highly probable that sooner or later the disease will make its appearance on the confines of Europe, and whenever this may happen, in consequence of its intimate commercial relations with the East, Constantinople is not likely to escape long. The historical facts of previous known pandemics show that in the first of them which occurred in the sixth century Constantinople (Byzantium) was infected from Pelusium in Egypt and from this city the disease spread widely over Europe. In the second pandemic which commenced in the eleventh century and was afterwards known in England as "The Black Death" the disease, similarly starting from the East, entered Europe by way of Constantinople.

The Mode of Spread of Plague.

The mode of extension of plague epidemics is well illustrated by the occurrences in the Punjab. First of all it is necessary to state that plague exhibits a seasonal periodicity which, though not the same in all places, tends to recur about the same time each year in any particular place. Thus in the Punjab it is only during the period from February to June that plague assumes epidemic proportions.

During the "free season," or that portion of the year in which the epidemic is not present, the disease may be introduced with impunity. For instance, during the period from August, 1906, to February, 1907, plague was imported on 15 occasions into the Jhelum district without it spreading to the inhabitants of the village or, as far as could be ascertained, causing rat mortality. As to the reason for this I am unable to offer any certain explanation, but the disease did not appear to remain latent until the arrival of the epidemic season, for no influence, either immediate or remote, could be traced to its importation at this time. In the month of February when the "plague season" commences a very different story is elicited. The occurrence of imported cases still continues and perhaps becomes more frequent, but now they give rise to rat mortality and to the occurrence of indigenous cases of the plague in man. The various modes by which this may take place will now be considered *seriatim*.

Spread by pneumonic plague.—It is a curious fact that pneumonic plague appears to be strictly confined to the first two months of the epidemic, a point recognised by Guy de Chauliac as long ago as 1348 but which recently does not appear to have attracted much attention, though its existence as a disease since its discovery by Lieutenant-Colonel L. F. Childe, I.M.S., in 1897 is a matter of common knowledge. As to the frequency with which it occurs, this appears to vary from year to year. During the present year, from personal investigations made at the time of the outbreak in 56 villages, pneumonic plague was responsible for the epidemic in nine, or 16 per cent., of the total. All of these occurred in the months of February or March—i.e., during the first two months of the epidemic. During this period it is responsible to a considerable extent for the spread of plague. Thus the effect of the introduction of one case was followed up and traced to five villages where, in spite of efforts made to stamp it out, it caused the death of 27 persons. But this was not all, for in addition it was also responsible for subsequent outbreaks of bubonic plague in two of these villages, with the result that 54 individuals also died from this form of the disease.

The history in all these cases is very similar and shows that the outbreak of the disease closely follows the arrival in the village of an individual suffering from, or incubating, pneumonic plague. It quickly spreads to the other inmates of the same house, often with such virulence that every individual is wiped out in the space of a few days. In my experience recovery rarely, if ever, takes place. The disease also spreads with alarming certainty to those who come in contact with the sick or tend the dying. By these it is spread to other households, who in turn infect their friends and relatives. From the evidence which has been collected it is impossible to resist the conclusion that the infection in pneumonic plague is direct from man to man but that it can also pass with ease from man to rat, and when this takes place an outbreak of bubonic plague on the usual lines follows.

Spread by the agency of man.—So much for the spread of the disease by pneumonic plague. This is, however, not the most usual course of events, for the history obtainable in the majority of cases is that at the onset of the plague season rat mortality was the first sign of the approaching epidemic. In the case of endemic areas no cause for this can be assigned, but in previously uninfected villages it will frequently appear that this has been preceded by the arrival of a person suffering from plague or who developed the disease shortly after arrival. A typical history of such cases is that about one week or ten days after the disease was thus imported by an infected individual dead rats began to be noticed in the vicinity of the house occupied by this individual.

The future course of the disease is characteristic. Starting from the house forming the original focus of infection the area in which dead rats are discovered gradually increases, then in the vicinity of the house in which dead rats were first found a plague case occurs. From this time the epidemic may be said to begin, at first slowly, with perhaps only one or two cases a day; subsequently, as the infected area becomes larger, the plague figures rapidly rise, so that 50, 100, or more fresh cases occur daily. After lasting usually from one month to six weeks it declines and finally ceases in the same order as it commenced.

It is usual to find in bubonic plague epidemics that the rat mortality precedes the occurrence of plague in man, thus giving a warning of approaching danger. Heralded in this manner by the rat epizootic, the epidemic can often be seen to travel from the house forming the original source of infection slowly up and down the street, frequently keeping for some time to one side of the road before crossing over.

In the epidemic in the Punjab this is, in my experience, by far the commonest history obtainable. Thus, of the 56 villages in which during the present year the cause of the outbreak was investigated at the time of its occurrence, in 36, or 64·2 per cent. of the total, the course of events conformed in all essential details to the above.

Spread by infected clothing or merchandise.—At the end of March, 1907, a small merchant visited the village of Lehri, a plague-free area, having come from an infected village some 40 miles distant. He stayed in the house of a relative for four days and then left for Rawal Pindi in his usual health. About two weeks after his departure dead rats were found in the house he had occupied. A few days later, on April 19th, a case of plague occurred in this house; subsequently a rat

Scotland, from about 1860 to 1882, when Koch discovered the bacillus of tuberculosis, owing to sanitary reform, coupled especially with the segregation of advanced cases, the disease had decreased even before the discovery of its immediate cause. Tuberculosis has been well called a dwelling or house disease, and, as pointed out by Koch, a person suffering from the disease became dangerous only when he was personally uncleanly, that is, did not disinfect his sputa, or became so helpless in consequence of the far-advanced state of the disease that he was no longer able to see to the suitable removal of the sputa, and, finally, that for the healthy the dangers of infection increased with the impossibility of avoiding the immediate neighbourhood of a dangerous patient—for instance, in densely inhabited rooms—and especially if these rooms were overcrowded and if they were badly ventilated and inadequately lighted. Let me give some interesting experiments on this question. If you take virulent sputum (expectoration) from a consumptive patient and deposit it on the window-ledge of a house that is insanitary—that is, badly ventilated—perhaps built directly on the clay and not cut off properly from the ground air and water—it will retain its power for months; nay, more, the ordinary processes of disinfection will not destroy the infective activity of such tuberculous material, indeed, it will survive freezing and thawing. On the other hand, when similar virulent expectoration is exposed in houses which have light and air with but little radiant sunshine for even two days its power for evil is gone. With light and ventilation it does not reach its dangerous state of dust before it is deprived of all power of doing harm, long-lived though the bacilli may be under certain insanitary conditions. Now sanitary reform of the houses does something else in addition to lessening the infectivity of the bacilli: it increases the resistance of the human body to their inroads. Those who have thoroughly investigated the question tell us how often cases of pulmonary consumption in our towns recur in certain houses and streets, how frequently one or more persons share the room or even the bed of a consumptive, how commonly the consumptive changes his house thus multiplying infection, and how rarely the house of a consumptive is disinfected either during his illness or after his death. I am bound to admit that the housing of the people in Ireland has improved, but in neither town nor country districts is it at all equal to what it is in England, and therefore want of sanitary progress in Ireland must, I think, be accepted as a cause for the prevalence of tuberculosis.

9. *The domestic or home treatment of the advanced cases of pulmonary tuberculosis.*—We now come to what I regard as the most potent cause which has prevented a lowering of the tuberculosis death-rate in Ireland and that is the domestic or home treatment of advanced cases of phthisis, because increasing experience demonstrates that with isolation of these advanced or "open" cases in any country the death-rate falls. Here are a few examples: In Stockholm, a city with a population of 300,000 (that is less than Belfast), over 400 cases of pulmonary tuberculosis are cared for in the hospitals of the city, with the result that in the last decades the death-rate from phthisis has gone down 38 per cent. As Koch puts it, we are to derive from this the lesson that the greatest stress is to be laid on this measure—namely, the placing of cases of pulmonary phthisis in suitable establishments—and far more care should be taken than hitherto that such patients do not die in their dwellings where they are for the most part in a helpless situation and inadequately nursed. In Prussia from 1876 to 1886 the pulmonary phthisis rate stood very high; since that time it has fallen from year to year and the decrease is now more than 30 per cent., that is about one-third; indeed, it has been calculated that though the population has meanwhile increased the number of people who die every year from pulmonary phthisis in Prussia is now about 20,000 less than it was 20 years ago, and Koch says that he is firmly convinced that the better provision for patients in the last stage of pulmonary phthisis—namely, the lodging of them in hospitals which is done in England as well as in Prussia to a comparatively large extent—has contributed most to the improvement. The very opposite line of practice—that is, the want of institutional treatment—is the cause why in Austria and Hungary the pulmonary phthisis death-rate still continues as formerly so high. In Berlin the death-rate from pulmonary consumption has decreased *pari passu* with the circumstance that during recent years more than 40 per cent. of the cases of pulmonary phthisis die in hospitals. A disease which comes near to tuberculosis in many respects is leprosy. In Norway, by isolating the most dangerous cases, the number of lepers has fallen from 3000 in 1856 to 500 at the end of 1905, and Koch, pointing to this as an example, emphatically declares that advanced cases of phthisis, those which are admittedly the most dangerous, ought to be lodged in hospitals. No man has devoted greater attention to this question than Dr. Newsholme, medical officer of health of Brighton, president of the Epidemiological Section of the Royal Society of Medicine, and one of the greatest living authorities in matters of public health. He made a most elaborate inquiry into the principal causes of the reduction of the death-rate from phthisis in different countries and came to the conclusion that the one common factor present in all places where the death-rate from this disease fell was the segregation of the patients in general institutions—that is, infirmaries or hospitals. In each country in which the institutional has replaced the domestic relief of destitution there has been a reduction of the death-rate from phthisis which is roughly proportionate to the change. Here are his interesting observations as to the increase of consumption in Ireland contemporaneously with its diminution in England. In the United Kingdom, he says, paupers receive two kinds of medical relief, outdoor or domestic and indoor or institutional (that is, workhouse or workhouse infirmaries). In England during 1861–65 the total number of paupers per 100,000 of the population was 4824, of whom 694 were in receipt of indoor relief and 4130 of outdoor relief. In 1901–03 the number of paupers per 100,000 of the population had diminished to 2218, and of these those receiving indoor relief were 688 (almost the same as 1861–65), while those in the receipt of outdoor relief were now only 1530. In Scotland there were during 1868–70, 3896 paupers per 100,000 of the population, of whom 253 got indoor and 3643 outdoor relief, while in 1901–03 the total number of paupers per 100,000 of population had sunk to 1922, of whom 242 (almost the same as in 1868–70) got indoor and only 1680 outdoor relief. In Ireland, on the other hand, during 1861–65 there were 1036 paupers per 100,000 of population, of whom 928 received indoor and 108 outdoor relief, while in 1901–03 the total number of paupers per 100,000 of the population had actually increased to 2272, and while those who got indoor relief were 947 (almost the same as in 1861–65), those receiving outdoor relief had increased to 1325. These figures, Dr. Newsholme thinks, and I am in entire agreement with him, give the key to the difference between Ireland and Great Britain. It is the enormous increase in the former country of pauperism relieved medically at home by the dispensary system which favours the treatment of even advanced cases of phthisis at home. Hence, Dr. Newsholme said, crowded and insanitary homes had their natural effect—when infectious patients have not been removed from them—of increasing the consumption death-rate. The fact that in Ireland the death-rate from consumption is higher among women than among men supports this view as it indicates domestic rather than industrial infection. The women (wives, sisters, and daughters) nursing the sick at home become infected. Further, it has been noted that consumptives do not remain nearly so long in the Irish workhouses as they do in the English, and even in Belfast where the most admirable arrangements were made in the union infirmary to treat consumptive patients in wards by themselves there is a common custom for the advanced (and most dangerous) cases to go home near the end to die. The same practice occurs, though I am glad to say to a less degree, with patients in the admirable sanatorium of the Belfast Union at Whiteabbey where in the verandahs in the present weather patients are sleeping. It has also been noticed that Irish Americans, who contract the disease when they emigrate, often come home to die, a practice which of course tends to spread the disease among the poor in Ireland; and those living in country districts know how often the people who have acquired the disease in Irish towns come in the end—often in the hope of recovery in their native air—to their old homes in the country to die.

It is interesting to note that there was no Poor-law provision in Ireland until 1838, and the Act passed then for the more effective relief of the destitute poor in Ireland, unlike the English Act, entirely prohibited outdoor relief. Before the end of 1840 127 unions were formed, each with its own workhouses, and the total 130 arranged for in the Act were soon afterwards established and relief could not be obtained except in these institutions. During the great famine and a bactericide. Haffkine's prophylactic should also be available in quantity so that it may be immediately distributed in case of necessity to all those willing to resort to it. As regards medicinal treatment no drugs in my hands have yielded results worthy of mention. Cases of plague appear to be best treated on general principles with the free exhibition of cardiac tonics. In India, at any rate, there is no doubt that a large number of unnecessary deaths take place from heart failure, due either to leaving the recumbent attitude too soon or sometimes directly to fear.

Jhelum, Punjab, India.

GRADUATED LABOUR IN PULMONARY TUBERCULOSIS.[1]

BY MARCUS S. PATERSON, M.B., B.S. DURH.,
M.R.C.S. ENG., L.R.C.P. LOND.,
MEDICAL SUPERINTENDENT, BROMPTON HOSPITAL SANATORIUM, FRIMLEY.

THE Brompton Hospital Sanatorium is situated on the Chobham Ridges, about two and a half miles from Frimley station, at an altitude of 380 feet. It contains 108 beds, 78 for men and 30 for women. Patients are not admitted directly to the sanatorium but are selected from the in-patients of the Brompton Hospital by the physicians of the hospital.

Early in 1905, while resident medical officer of the Brompton Hospital, I was asked by the committee to organise the new sanatorium which was on the point of completion. I had observed that many tuberculous patients who had followed their ordinary occupations up to the time of admission were in a very fair condition of health. The case of a navvy may be cited as an example. He had worked for 40 hours almost without a rest, altering a water main, a few days previously, and although he had a considerable amount of disease, was apparently none the worse for such arduous work. It occurred to me that, if some consumptive persons under adverse circumstances, and without any medical guidance, could act thus without apparent injury they ought, under ideal conditions and with the work carefully graduated in accordance with their physical state, to be able to undertake useful labour. On this assumption manual work should be of great advantage to patients undergoing treatment in a sanatorium, as, first, it would do much to meet the objection that members of the working classes are liable to have their energy sapped, and to acquire lazy habits by such treatment; secondly, it would make them more resistant to the disease, by improving their physical condition; and thirdly, would enable them by its effect upon their muscles to return to their work immediately after their discharge. The idea was a new one and in opposition to the generally accepted medical opinion on the subject. It had, however, been shown by Dr. Otto Walther of Nordrach that excellent results could be obtained by graduated walking exercise, especially when, in suitable cases, this exercise was pushed to the extent of walking 20 miles a day. In this form of exertion, however, the muscles used were chiefly those of the lower limbs. I had it in mind to employ also the upper limbs which are supposed to have a more direct influence on the expansion of the lungs. The objections naturally raised to this method of treatment were: (1) that the disease would become active again under the strain; and (2) that the exertion would tend to produce hæmoptysis.

At the outset great care had to be exercised, not only from the fear that as the views which had led to the adoption of the method were possibly unsound, harm might be done, but also because the patients did not take kindly to the work, it being absolutely contrary to their preconceived views of treatment suitable to their condition. Some of them imagined for a time that it was not designed for their benefit but purely for the advantage of the institution, and they regarded me rather as a labour master trying to get so much work out of them than as a medical man who was endeavouring to cure their disease. Care was especially necessary in the selection of patients for the work, as had there been a case of severe hæmoptysis, or of high fever or pleurisy, it would probably have been impossible to convince the patients that the method was sound and they would have refused to work.

Walking exercise was first ordered, the distance being gradually increased up to 10 miles a day. When a patient had reached this stage he was given a basket in which to carry mould for spreading on the lawns, &c. No case of hæmoptysis or of pyrexia occurred among these patients. When they had been on this grade with nothing but beneficial results for from three weeks to a month, they were given boys' spades with which to dig for five minutes, followed by an interval of five minutes for a rest. After a few weeks several of the patients on this work, who were doing well, were allowed to work as hard as possible with their small spades without any intervals for rest. As they had all improved on this labour larger shovels were obtained, and it was found that the patients were able to use them without the occurrence of hæmoptysis or of a rise of temperature. About this time many of the patients were feeling so well that it became necessary to restrain them from doing too much. The tradition of absolute obedience to the orders as to the amount of work to be done had not yet been firmly established, and one of the patients who had improved most of all was found wheeling a heavy barrow full of sand without permission. When admonished for infringing his instructions he replied that he felt quite fit for such work, and as he would have to leave shortly and do hard work he wanted to get into condition for it. This argument appeared to be sound, and as he was willing to take the risk he was allowed to continue to wheel the barrow for the full labour period, which at that time was three hours a day. He suffered no ill-effects, but, on the contrary, did exceedingly well, and has since been at work for over two years. It was thus shown that a tuberculous man could, in certain instances, do heavy manual labour and continue to improve in health. I accordingly decided to work out a carefully graduated scale of labour.

At the end of the first six months a great advance had been made, for the tradition of work as a method of treatment was firmly established and the patients saw clearly that it was for their own benefit. The extension of the system required great care and minute supervision, for the patients, far from objecting to, or attempting to shirk, their appointed labour, now had a tendency to do more than they were ordered. Harder work was first prescribed for those patients who could be trusted. It was found that they could gradually be trained to use the heaviest spades, shovels, and 5-pound pickaxes with advantage to their physical condition, and without any attack of hæmoptysis or rise of temperature. The patients all expressed the opinion that the work did them good and that the harder they worked the better they felt. Many patients have since written to say that they date their improvement from the commencement of the labour and that they think that the hardest work did them the most good. Within the first year there were several patients who would, despite all instructions, over-exert themselves and use heavier tools than they should have done. In most instances no serious harm resulted but several of them developed fever and subsequently pleurisy. Pleurisy, indeed, appears to be a frequent result of any excessive work. One of these patients was laid up for nearly two months and was much worse at the end of that time, although eventually he did well and is now at work, but the extent of his disease was increased by the over-exertion. The necessity of absolute obedience to the medical officer's orders was firmly established by such cases. Each patient on admission is told that he will be treated by prescribed rest and exercise and that as he does not himself know the amount of rest or exercise which he requires he must do exactly as he is told, and that whilst harm will result if he does too much he will not receive proportionate benefit if he does too little. It is also pointed out that he must consider himself under treatment for the whole day, the amount of rest and exercise being definitely fixed for the 24 hours.

Details of the System of Graduated Labour.

1. *Results of physical examination.*—Each patient on arrival at the sanatorium is examined and the extent of the disease as indicated by physical signs is noted. The patients are then divided into two classes: (*a*) Those with early disease—i.e., slight signs in one or two lobes; and (*b*) those with more extensive disease—i.e., with either extensive infiltration of one lobe, or infiltration of two, three, or four lobes of some duration, the lesions often showing signs of fibrosis.

2. *General condition.*—The next points noted are the facial expression and the general physical development of the

---

[1] A paper read before the Medical Society of London on Jan. 13th, 1908.

For the very early cases, in the hope of arresting the disease, sanatoriums should be erected, and one might suffice for two or three counties. These sanatoriums should be made of some cheap material, say wood, so as to be *burned* at times, and not of costly brick or stone, and the cheaper they are the better, if only efficient in other respects. For those intermediate between the early and the advanced cases who are able still to be at their work but too advanced for sanatorium treatment the greatest efforts should be made to instruct them (and indeed the whole people) as to the danger of tuberculosis and how much they can do by carefully disinfecting their expectoration and by not indulging in the filthy and dangerous habit of spitting, which should be made an offence punishable by a heavy fine. Everything that tends to educate the people of Ireland as to the danger of tuberculosis, such as lectures and exhibitions—like the one that is here—is to be encouraged, and I believe the visits among the poor in order to instruct them as to what is now known in regard to tuberculosis (especially as to cleanliness, sleeping in a room by themselves, and the treatment of the sputum) by the members of the various branches of the Women's National Health Association of Ireland will be of enormous aid. In the larger towns a dispensary for tuberculous patients should be instituted.

3. We must educate the people more and more as to the importance of keeping their houses clean and sanitary, well ventilated, not overcrowded, and so situated as to be properly lighted by the sun, and they must be taught what measures they can adopt to prevent the onset and spread of the disease; in other words, we must teach the people that they themselves have it in their own power largely to control the disease.

4. Temperance in all things should be inculcated, as well as the use of nourishing properly cooked food, and the laws of hygiene and temperance should be taught in the primary schools, which should be medically inspected.

5. As to meat, every person, rich or poor, should have a guarantee that all meat used by him has been inspected, and the veterinary inspectors in my opinion should be State officials. There should be public abattoirs or slaughterhouses and all private ones should be abolished. The same type of inspection of meat should prevail in town and country.

6. Considering the teaching of the recent report of the Royal Commission appointed to inquire into the relations of human and animal tuberculosis all cows with tuberculous disease of the udders should be forthwith slaughtered and those that react to the tuberculin test should be branded. The control of our milk-supply is so important that I believe it will never be managed rightly until the State takes it under its care, the regulations for inspection of the dairies (medical and veterinary), and for the clean production, conveyance, and distribution of milk being enforced by experts *responsible* to the State. It is time the truth was realised that the conditions which maintain health in the cows are very similar to those which we advise for the human race—that is, fresh air, proper ventilation, sunlight, suitable food, pure water, and cleanliness. The Department of Agriculture and Technical Instruction for Ireland and the various agricultural shows and societies, I trust, will unite with the Government in devising means for getting rid of tuberculosis in animals. I admit all these measures I have suggested will cost money and it is clear compensation for loss of cattle will have to be paid; but are we really to speak of money when, on the other hand, we contemplate almost 12,000 lives lost annually (with 120,000 ill) through a disease which science and experience show us is preventable? What money has been expended freely to stamp out cattle plague, foot and mouth disease, pleuro-pneumonia, glanders, swine fever, &c.? Are human beings of less value? To those who think that to rid Ireland of the white plague is an impossible task I reply in the words of the Spanish proverb in Don Quixote, "The beginning of health is to know the *disease*." We are now thoroughly acquainted with tuberculosis as we never were before and the experience of other countries shows what could be done in Ireland by combined effort. We are no longer in the doubtful position of the sailor of whom Ovid writes: "Hope it is which makes the shipwrecked sailor strike out with his arms in the midst of the sea, even though on all sides he can see no land."

> "Haec [spes] facit, ut videat cum terras undique nullas,
> Naufragus in mediis brachia jactet aquis."

We now see other lands where years ago tuberculosis was far more prevalent than with us, they have since largely got rid of it, why can we not profit by their experience and follow their methods?

I *rejoice* to know that the public of Lurgan are joining the rest of their fellow countrymen in this glorious campaign to free our land from a plague that too long—largely owing to *our* want of education—has prevailed among us; but now that our mothers and our wives and our sisters have been awakened—thanks to the splendid efforts of one of the ablest, most benevolent, and large-hearted women that *ever* lived, Her Excellency the Countess of Aberdeen—we are all full of hope that a better time is in store for *our* beloved country and that the cloud and the stigma that hang over Ireland at present for her high mortality from a preventable disease will in time be completely removed.

THE EPIDEMIOLOGY OF PLAGUE.

WITH SPECIAL REFERENCE TO ITS MODE OF SPREAD AND THE MEANS BY WHICH IT MAY BE COMBATED.[1]

BY CLIFFORD ALLCHIN GILL, M.R.C.S. ENG., L.R.C.P. LOND.,

CAPTAIN, INDIAN MEDICAL SERVICE; PLAGUE MEDICAL OFFICER, JHELUM DISTRICT, PUNJAB, INDIA.

THE prevention of plague, even if judged merely from the hygienic and epidemiological standpoint, involves difficult problems which render the subject one of peculiar interest to those who in various lands have the care of the public health. My knowledge of the complicated bearings of the question is derived from the fact that for the past two years I have been studying these problems as they present themselves in the epidemic which is creating such havoc in India. One of the objects of this paper will be to show that there are reasonable grounds for believing that the pandemic of plague now chiefly affecting India may, in the near future, extend itself widely over the world, and by again visiting Europe cause another of those devastating epidemics with which history has made us acquainted.

On the present occasion I will keep as much as possible to the purely practical side of the question, without entering into the clinical, bacteriological, or other aspects of plague.

The subject may be conveniently arranged under the following three heads. 1. The course of the present pandemic of plague from its origin to the present time. 2. The mode of spread of the disease: (*a*) within an infected area, and (*b*) from an infected to an uninfected area. 3. The methods by which the disease may be combated: (*a*) prophylactic measures in uninfected areas, and (*b*) preventive measures in the epidemic zone.

The Course of the Present Pandemic.

For a proper appreciation of the dangers of the situation in which we are placed it is necessary to consider the course and history of the present pandemic from its origin to the present time. Two well-marked centres of endemic plague are now recognised to exist and the forms of the disease to which they respectively give rise are not in all respects alike. The differences, however, are not sufficiently distinct to warrant them being termed "varieties"; they are more correctly spoken of as different "strains" of the same disease and they have been named in accordance with their geographical distribution (1) the Western Asian strain and (2) the Indo-Chinese strain. Of the differences in their characters the two most striking are the greater virulence and power of extension of the Indo-Chinese "strain" and its marked association with rat mortality.

Plague has long been known to exist in Western Asia, but on account of its mildness and lack of power of extension it has come to be regarded with indifference, and public opinion in Europe has come to regard the disease as a purely Eastern one and as possessing no significance for modern Europe. It must be remembered, however, as a very important point, that the disease with which we have to deal nowadays is the virulent and diffusible Indo-Chinese strain of plague and not the milder and less important Western Asian strain. So far as is known the Indo-Chinese strain of plague *originated* in Yunnan, a province of Western China, about the year 1860, though in all probability it had existed in this little known province some patient. These points should always be considered together with the physical signs, as a patient with tubercle bacilli in his sputum may look very ill and have marked wasting and poor development, even though no physical signs of disease are found on examination of the chest. Such a patient is quite unfitted for much, if any, exercise, whereas a patient looking fairly well, of good development, but with physical signs indicating that even as many as four lobes are affected, may be quite capable of considerable muscular exertion. It must be remembered that the resisting power of a patient with a very limited lesion is practically an unknown quantity and has to be determined, whereas a patient with a lesion involving four lobes who has continued at work for some time and has remained, in spite of the disease, in fair condition probably had a good initial resisting power.

---

[1] Abstract of a paper contributed to the International Congress of Hygiene and Demography, held at Berlin in September, 1907.

3. *Presence or absence of fever.*—The next point for consideration is the temperature, which is taken in the mouth. Should this be, or have been, 99° F. or over during the week preceding admission to the sanatorium the patient is put to bed after the journey. So long as the temperature remains at 99° in the case of men or 99·6° in the case of women the patient is not allowed up for any purpose. Work is prohibited and reading is the only recreation permitted. Naturally the object of this stringent rule is to try to check the activity of the disease. I consider that if a patient with few signs of disease, when absolutely at rest in bed, still has a temperature of 99° active disease is present. Such patients are usually kept together in one ward for the sake of cheerfulness, male and female patients being of course in separate wards. After the temperature has been normal for a week or ten days the patient is allowed up for dinner but returns to bed as soon as the meal is finished. So long as the temperature is unaffected by this exertion the patient is gradually allowed up for longer and longer periods. In practice it is found that the longer the time the patient has had to stay in bed before his temperature subsides to, and remains at, the normal level the more protracted must be the period before he can be allowed to remain up for a whole day in safety. When this stage is reached the patient commences to work with the fingers, sewing, making mats, mops, &c.

4. *Exercise.*—If the general condition and appetite are good and the patient is feeling well after from 10 to 14 days of this treatment he is allowed to walk half a mile a day for a week. He then gradually goes through the grades of exercise subsequently to be described as suitable for those patients whose temperature is normal. Patients with apparently limited disease, but who are in poor general condition and without fever, are allowed to be up all day but are not permitted to take further exercise than is entailed by walking to and from the dining hall for their meals. The remainder of the day is spent resting, and work entailing no physical exertion is allowed with the sole object of occupying their minds. As their condition improves they are allowed to walk half a mile a day, then a mile a day, and so on, until a distance of six miles a day is achieved. The rate of increase in the amount of exercise depends upon such factors as the patient's disposition, weight, and appetite. It is not possible to make a definite statement as to the number of days during which the patient should be set to walk half a mile, two miles, four miles, and so on, as each case requires to be judged on its merits and on the response to treatment. A patient allowed to walk a mile a day for 14 days may be doing well yet the increase of half a mile may cause the temperature to rise to 99°. If this occurs he is then ordered to rest for a day or so before recommencing with a mile a day. It will thus be seen that the exertion required for each grade of work acts as a test not only of the fitness of the patient for such labour but also of his fitness for an increased amount of exercise.

The grades of work may be summarised as follows: (A1) Walking from ½ mile to 10 miles daily; (1) carrying baskets of mould or other material; (2) using a small shovel; (3) using a large shovel; (4) using a pickaxe; and (5) using a pickaxe for six hours a day. Patients in Grades 1, 2, 3, and 4 work for four hours a day.

Grade 1.—Basket work is subdivided into three sections. In the first the patient carries a load of about 12 pounds in weight a distance of 50 yards up a gradient of 1 in 10·7—i.e., rising 14 feet in that distance. Such patients carry in a day 80 loads, or, in other words, they will carry 8½ hundredweights a distance of 50 yards and return for a distance of 4000 yards with the empty basket. In the second section the weight carried is about 18 pounds, the conditions being the same, and these patients carry about 13 hundredweights per day. In the third section the weight carried is 24 pounds. A patient on this work carries during the day about 17½ hundredweights for the same distance.

Grade 2.—The small shovel is the ordinary coal scoop provided with a long handle. Patients commencing on this grade of labour will dig two tons of earth a day and raise it seven feet into a cart, and as they increase in strength will in a day lift about four tons the same height.

Grade 3.—The large shovel is the ordinary shovel used by a navvy. Patients on this grade will dig and lift about six tons a day a distance of seven feet.

Grade 4.—Pickaxe work is the hardest work possible, and consists of breaking unbroken ground, excavating, &c.

Concrete mixing comes under the heading of pickaxe work, as although the large shovel is used the work is heavier than moving sand or mould. Each man moves about ten tons a day and *has to keep going* or he stops the whole of the men, whereas on the other work he can take his own time.

When a patient has been on a grade of labour for about three weeks his fitness for harder work is considered. If the temperature has been normal, the weight satisfactory, the appetite good, and if he is feeling well (this is to be determined by watching the way in which he performs his work) then he is put on harder work. Here may be noted an interesting psychological effect of physical improvement. Many patients on their arrival are somewhat remarkable for a certain sullen and apathetic attitude, but as soon as their physical condition undergoes amelioration all traces of gloom and depression leave them and they become transformed into lively, cheerful individuals. After three weeks it is usually found that the patient who is working within his strength is of his own accord working harder than he did when first placed in that particular grade. This is specially noticed with "basket men," who carry about 8 pounds weight of earth. The quantity is gradually increased and finally the patient is allowed to fill his own basket, which he usually does to its fullest capacity.

I consider the basket grade the most important of all, and patients as a rule spend far more time in this grade than in any other. I regard it as the connecting link between walking and work. It does not entail much exertion and yet brings into use nearly all the muscles of the body and so fits the patient for light work. I am always careful to have a definite and apparent object in this and all work, so that the patients can see the result of their labour. Patients hate nothing more heartily than work which is of no practical utility.

Patients who have successfully gone through the above grades and worked for six hours a day are three weeks before their discharge put to work at their trades, if they have a trade, in order that the muscles used in their particular work may become accustomed to it before they leave the sanatorium. These examples are given to show approximately what amount of energy is exerted in each grade of labour. Patients are not confined to the work enumerated above but are given other work corresponding in severity to the use of the tools mentioned. For instance, painting, hoeing, and chopping wood are equal to the work of Grade 2. Sawing trees into firewood is equal to the work of Grade 3. Planing wood is equal to the work of Grade 4. Any form of labour can be utilised, but an estimate must be made of the amount of energy which it involves. Patients who have reached the stage of walking four miles a day or any higher grade of work make their own beds, change their bed linen, clean their wards and windows, polish the floors of adjacent corridors, and keep the dining halls clean and the brasswork bright.

The grades of exercise and work for the women are similar to those for the men, but the various implements, such as baskets, shovels, &c., are of smaller size. These patients are not allowed to work as hard as the men and consequently do not accomplish as much in the same time. They also keep in order their own part of the grounds, cultivate a small kitchen garden, and, in addition, they have charge of the poultry. The final grade corresponding to the hard navvy work of the men consists of scrubbing work indoors.

One of the first indications that a patient is taking too much exercise is that he loses his appetite and suffers from slight headache. If he continues to do the same amount of work the temperature will rise to 99°. This temperature is the danger signal and any patient who has a temperature of 99° and is suffering from the slightest headache is immediately ordered to bed. In cases of extensive disease—e.g., of

For the very early cases, in the hope of arresting the disease, sanatoriums should be erected, and one might suffice for two or three counties. These sanatoriums should be made of some cheap material, say wood, so as to be burned at times, and not of costly brick or stone, and the cheaper they are the better, if only efficient in other respects. For those intermediate between the early and the advanced cases who are able still to be at their work but too advanced for sanatorium treatment the greatest efforts should be made to instruct them (and indeed the whole people) as to the danger of tuberculosis and how much they can do by carefully disinfecting their expectoration and by not indulging in the filthy and dangerous habit of spitting, which should be made an offence punishable by a heavy fine. Everything that tends to educate the people of Ireland as to the danger of tuberculosis, such as lectures and exhibitions—like the one that is here—is to be encouraged, and I believe the visits among the poor in order to instruct them as to what is now known in regard to tuberculosis (especially as to cleanliness, sleeping in a room by themselves, and the treatment of the sputum) by the members of the various branches of the Women's National Health Association of Ireland will be of enormous aid. In the larger towns a dispensary for tuberculous patients should be instituted.

3. We must educate the people more and more as to the importance of keeping their houses clean and sanitary, well ventilated, not overcrowded, and so situated as to be properly lighted by the sun, and they must be taught what measures they can adopt to prevent the onset and spread of the disease; in other words, we must teach the people that they themselves have it in their own power largely to control the disease.

4. Temperance in all things should be inculcated, as well as the use of nourishing properly cooked food, and the laws of hygiene and temperance should be taught in the primary schools, which should be medically inspected.

5. As to meat, every person, rich or poor, should have a guarantee that all meat used by him has been inspected, and the veterinary inspectors in my opinion should be State officials. There should be public abattoirs or slaughter-houses and all private ones should be abolished. The same type of inspection of meat should prevail in town and country.

6. Considering the teaching of the recent report of the Royal Commission appointed to inquire into the relations of human and animal tuberculosis all cows with tuberculous disease of the udders should be forthwith slaughtered and those that react to the tuberculin test should be branded. The control of our milk-supply is so important that I believe it will never be managed rightly until the State takes it under its care, the regulations for inspection of the dairies (medical and veterinary), and for the clean production, conveyance, and distribution of milk being enforced by experts responsible to the State. It is time the truth was realised that the conditions which maintain health in the cows are very similar to those which we advise for the human race—that is, fresh air, proper ventilation, sunlight, suitable food, pure water, and cleanliness. The Department of Agriculture and Technical Instruction for Ireland and the various agricultural shows and societies, I trust, will unite with the Government in devising means for getting rid of tuberculosis in animals. I admit all these measures I have suggested will cost money and it is clear compensation for loss of cattle will have to be paid; but are we really to speak of money when, on the other hand, we contemplate almost 12,000 lives lost annually (with 120,000 ill) through a disease which science and experience show us is preventable? What money has been expended freely to stamp out cattle plague, foot and mouth disease, pleuro-pneumonia, glanders, swine fever, &c.? Are human beings of less value? To those who think that to rid Ireland of the white plague is an impossible task I reply in the words of the Spanish proverb in Don Quixote, "The beginning of health is to know the disease." We are now thoroughly acquainted with tuberculosis as we never were before and the experience of other countries shows what could be done in Ireland by combined effort. We are no longer in the doubtful position of the sailor of whom Ovid writes: "Hope it is which makes the shipwrecked sailor strike out with his arms in the midst of the sea, even though on all sides he can see no land."

> "Haec [spes] facit, ut videat cum terras undique nullas,
> Naufragus in mediis brachia jactet aquis."

We now see other lands where years ago tuberculosis was far more prevalent than with us, they have since largely got rid of it, why can we not profit by their experience and follow their methods?

I rejoice to know that the public of Lurgan are joining the rest of their fellow countrymen in this glorious campaign to free our land from a plague that too long—largely owing to our want of education—has prevailed among us; but now that our mothers and our wives and our sisters have been awakened—thanks to the splendid efforts of one of the ablest, most benevolent, and large-hearted women that ever lived, Her Excellency the Countess of Aberdeen—we are all full of hope that a better time is in store for our beloved country and that the cloud and the stigma that hang over Ireland at present for her high mortality from a preventable disease will in time be completely removed.

THE EPIDEMIOLOGY OF PLAGUE.

WITH SPECIAL REFERENCE TO ITS MODE OF SPREAD AND THE MEANS BY WHICH IT MAY BE COMBATED.[1]

BY CLIFFORD ALLCHIN GILL, M.R.C.S. ENG.,
L.R.C.P. LOND.,

CAPTAIN, INDIAN MEDICAL SERVICE; PLAGUE MEDICAL OFFICER,
JHELUM DISTRICT, PUNJAB, INDIA.

THE prevention of plague, even if judged merely from the hygienic and epidemiological standpoint, involves difficult problems which render the subject one of peculiar interest to those who in various lands have the care of the public health. My knowledge of the complicated bearings of the question is derived from the fact that for the past two years I have been studying these problems as they present themselves in the epidemic which is creating such havoc in India. One of the objects of this paper will be to show that there are reasonable grounds for believing that the pandemic of plague now chiefly affecting India may, in the near future, extend itself widely over the world, and by again visiting Europe cause another of those devastating epidemics with which history has made us acquainted.

On the present occasion I will keep as much as possible to the purely practical side of the question, without entering into the clinical, bacteriological, or other aspects of plague.

The subject may be conveniently arranged under the following three heads. 1. The course of the present pandemic of plague from its origin to the present time. 2. The mode of spread of the disease: (*a*) within an infected area, and (*b*) from an infected to an uninfected area. 3. The methods by which the disease may be combated: (*a*) prophylactic measures in uninfected areas, and (*b*) preventive measures in the epidemic zone.

The Course of the Present Pandemic.

For a proper appreciation of the dangers of the situation in which we are placed it is necessary to consider the course and history of the present pandemic from its origin to the present time. Two well-marked centres of endemic plague are now recognised to exist and the forms of the disease to which they respectively give rise are not in all respects alike. The differences, however, are not sufficiently distinct to warrant them being termed "varieties"; they are more correctly spoken of as different "strains" of the same disease and they have been named in accordance with their geographical distribution (1) the Western Asian strain and (2) the Indo-Chinese strain. Of the differences in their characters the two most striking are the greater virulence and power of extension of the Indo-Chinese "strain" and its marked association with rat mortality.

Plague has long been known to exist in Western Asia, but on account of its mildness and lack of power of extension it has come to be regarded with indifference, and public opinion in Europe has come to regard the disease as a purely Eastern one and as possessing no significance for modern Europe. It must be remembered, however, as a very important point, that the disease with which we have to deal nowadays is the virulent and diffusible Indo-Chinese strain of plague and not the milder and less important Western Asian strain. So far as is known the Indo-Chinese strain of plague originated in Yunnan, a province of Western China, about the year 1860, though in all probability it had existed in this little known province some tested by tuberculin. These nine cases are left out as to their after-results, so that the number to be accounted for is 155. Of these, 135 are at work, nine have not reported themselves, nine are not at work, and two are dead.

---

[1] Abstract of a paper contributed to the International Congress of Hygiene and Demography, held at Berlin in September, 1907.

A point which I wish to emphasise is that all of the above patients returned to their previous occupations whatever they happened to be, and not to light out-door work. To advise the latter has always seemed to me like recommending plenty of good food and milk to those who are practically penniless: excellent advice but impossible to carry out.

Some ten months ago Dr. A. C. Inman suggested to me that the explanation of the satisfactory results obtained from the system of graduated labour was that the work caused an inoculation of the patient by his tuberculin. This theory, the origin of which is given in Dr. Inman's paper, was supported by the fact that after a rise of temperature, and therefore an auto-inoculation, patients were often better than before, and that patients who were not improving on a certain grade of work did improve on harder work. The theory is that the harder work gives rise to an auto-inoculation whereas the lighter work fails to do so. For the past ten months I have used this as a working hypothesis in determining the suitability of a patient for any particular grade of labour and have found it to be of very great assistance. The method entails a more careful graduation of the labour, as two important questions have to be answered: 1. Is the patient doing work which is too hard? 2. Is he doing sufficient work to keep himself properly inoculated? In other words, suitable work has to be found for what is regarded as the exact medical condition of each patient. When Dr. Inman commenced to examine the bloods of the patients and required cases of a certain kind I was able to find without any difficulty examples of cases required: as, for instance, a patient who was auto-inoculating himself slightly, or again one with a high opsonic index. The same is true of patients with a normal index, also of patients who from excessive auto-inoculation had low indices, and of patients whose index was constantly low. The results of the examinations of the blood were most convincing, because they bore out so exactly the condition of the patient as determined by clinical observation. One case was especially useful. It was that of a man who was regarded as possibly fit for harder work but whose condition was such that it was judged to be unwise to take the risk of increasing his task. The blood was examined and his index found to be practically normal. He was then put on harder work for a week and the index again taken. Again it was practically normal. He was then put on the heaviest work and performed it without harm. In a case of this kind the opsonic index proves an invaluable guide, saving perhaps months of time, by determining within a week that the patient is fit for the hardest work, when clinically we should hesitate to come to such a conclusion. Dr. Inman's work, so far as it has gone, confirms the value of graduated manual labour in the treatment of pulmonary tuberculosis and has done so in a manner that could only be determined by a further trial lasting over several years.

The points so far determined appeared to me to be as follows. 1. Suitably selected patients can be gradually trained to do the hardest navvy work for six hours a day, the result being that their general condition is much improved whilst some lose both their sputum and their tubercle bacilli. 2. Certain patients who do not improve on light work show marked improvement on harder work. 3. Patients who have slightly over-exerted themselves and are kept at rest for the few following days are subsequently not only not worse but may be in their own opinion better.

My observations so far lead me to the conclusion that graduated labour is a definite medical treatment for cases of pulmonary tuberculosis and raises the general health and resisting power of the patients.

Finally, I should wish to express very strongly the opinion that the combination of rest, pure air, and over-feeding is not the only treatment for chronic pulmonary tuberculosis and equally strongly to advise those physicians who may adopt these suggestions contained in this paper to pay particular heed to the word *graduated* and to remember the importance of the temperature of 99° F.

Frimley.

A NEW MEDICAL PASHA.—Professor Wieting, director of the Osman Clinical Hospital, Gulhane, Constantinople, has been raised to the dignity of a Turkish Pasha.

THE EFFECT OF EXERCISE ON THE OPSONIC INDEX OF PATIENTS SUFFERING FROM PULMONARY TUBERCULOSIS.[1]

BY A. C. INMAN, M.A., M.B. OXON.,
SUPERINTENDENT OF THE LABORATORIES OF BROMPTON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, LONDON.

(From the Bacteriological Laboratory of the Brompton Hospital.)

THE study of the part played by the blood as a protective agent in bacterial infections has recently entered upon a new phase. Hitherto the subject had been mainly one of scientific interest only; the results obtained and the principles and theories evolved had been for the most part confined within the walls of the laboratories. The phagocytic action of the white corpuscles and its rôle in immunity had ceased to interest the clinician. The discoveries of Ehrlich, brilliant as they were, were appreciated by few who were not pathologists, the "side-chain theory" with its difficult nomenclature having but little effect on bedside medicine. But the publication of Sir Almroth Wright's investigations and the principles of immunity expressed by him have not only thrown a new light upon clinical problems hitherto in obscurity but have produced results and suggested inquiries of great importance in the domain of practical medicine. Wright, by a modification of Leishman's technique, completely separated all three elements necessary for the phenomenon of phagocytosis—viz., white corpuscles, serum, and bacteria—and was thus able to investigate the rôle played by the blood in bacterial infections more fully than had previously been possible. In his lecture before the Harvey Society of New York he shows that as regards active immunisation there are three great agencies by which immunising responses can be evoked in the organism: (1) the inoculation of bacterial vaccines; (2) artificially induced auto-inoculations; and (3) spontaneous auto-inoculations. In previous publications he had expounded the principles of vaccine therapy and had been able to show by means of curves constructed from the opsonic indices of patients vaccinated against their infection the definite train of events which follow upon a single inoculation. He has defined these successive phases as the negative phase, the positive phase, and the phase of maintained high level. Freeman, working in Wright's laboratory, next opened up a new field for investigation by his observations on the effect of massage on gonococcal joints. Owing to this work it has been possible "*to show that auto-inoculations follow upon all active and passive movements which affect a focus of infection and upon all vascular changes which activate the lymph-stream in such a focus.*" Further, it is obvious that, as Wright puts it, "where in association with a bacterial invasion of the organism bacteria or bacterial products pass into the general lymph- and blood-stream intoxication effects and immunising responses, similar to those which follow upon the inoculation of bacterial vaccines, must inevitably supervene." And it is by the agency of such auto-inoculations that nature achieves curative effects in bacterial infections. The far-reaching importance of these observations on spontaneous and artificially induced auto-inoculations decided me to investigate the part played by auto-inoculation in pulmonary tubercle. Moreover, it is obviously desirable before attempting to treat a disease, however rationally, to try to find out what the body is doing of itself and to what extent extraneous circumstances, such as movements, influence these attempts on the part of the body.

The technique.—In these experiments the technique as carried out by Wright and Douglas has been followed. 1. The corpuscles were very carefully washed in sterile salt solution (0·85 per cent.) after the first centrifugation so as to get rid of all traces of serum and citrate solution. 2. The emulsion. A culture, obtained from a solid medium, and suspended in 1·5 salt solution was used. 3. The serum was always collected in Wright's tubes and the blood allowed to clot at room temperature. The blood was always examined the same day as it was drawn, usually within five or six hours. Before each experiment a "trial trip" was made with the normal serum with a view of seeing that all the epizootic followed by a small epidemic, radiating from this house, spread through the village. No other person was stated to have recently visited the village, which occupies a very isolated position, and was at that time at least 20 miles distant from the nearest infected village. This illustration strongly suggests that the disease was conveyed to the village on the clothing or person of the man or in his baggage, while he himself escaped the disease. In the 56 epidemics analysed, this mode of infection occurred in two, or 3·6 per cent. of the total, and in six others, or 10·8 per cent. of the total, it was thought to have taken place, but accurate information was lacking.

---

[1] A paper read before the Medical Society of London on Jan. 13th, 1908.

Spread by the migration of rats.—A fourth mode of spread of the disease has been described—namely, that under the influence of the panic occasioned by the epizootic migration of rats from village to village takes place with the result that the infection is conveyed in this manner. My observations on the common rat of India, the black rat (mus rattus), go to show that, as regards this rodent, the spread of the disease between villages can rarely if ever take place by this means. The accidental transportation of infected rats in ships and merchandise is, however, a fruitful source of the disease being conveyed long distances.

A few words are necessary as to the manner in which man becomes infected. This we have seen in the case of pneumonic plague is "direct" from sick to healthy, in the case of the bubonic variety a link between man and the rat appears necessary; that this is supplied, in the majority of cases, by the rat flea, pulex cheopis (Rothschild), the work of the Indian Plague Commission leaves but little room for doubt. But this is not the only mode of infection, as accidental inoculation in the case of man, feeding experiments and infection through the shaved skin in the case of animals abundantly prove. Any method by which the bacillus is introduced into the body is capable of producing the disease. More knowledge is required concerning the habits of the rat flea before its influence can be fully determined, but at first sight the fact that infection may take place in a variety of ways and that in the most virulent type of the disease—pneumonic plague—this insect is not concerned, would suggest that the rôle of the rat flea in the transmission of the disease is a passive one. It has recently been suggested that the occurrence of the annual epidemics are dependent on and associated with the prevalence of the rat flea, but though some relationship does exist between flea prevalence and plague prevalence, this does not appear to warrant the assumption that the flea is anything more than one of the factors in the case.

Preventive Measures.

Up to the present the measures which have been chiefly relied on, and which obtained official recognition at the International Sanitary Convention of Paris (1903), have been confined to the prevention of the importation of the disease and to methods of stamping it out when it has occurred on board ship or elsewhere. These no doubt are very necessary, but they are not sufficient, for it is not always possible to detect every case of plague even in the most favourable circumstances, and, furthermore, a case of human plague is not an essential preliminary to an outbreak of the disease. It is for this reason that the large sums of money spent in the past on disinfection and similar measures have not been attended with success, with the result that not only has the progress of the disease not been arrested, but all anti-plague measures have fallen into discredit.

It therefore becomes necessary to consider what other means are available to remedy this defect. One of the essential requisites is that every sanitary authority should possess a special plague department, the sole duty of which it should be to frame and to carry out the measures suited to the requirements of the area under its control.

The chief means of the spread of bubonic plague from place to place is, we have seen, by the agency of man, and methods designed for the protection of uninfected areas may therefore be directed to the control and supervision of individuals coming from infected areas. It is chiefly on such control that most anti-plague measures in the past have been based but they have not met with invariable success. As regards bubonic plague they are open to obvious objections—namely, that adequate supervision is extremely difficult and that they take no account of the possibility of infection by infected merchandise, clothing, or rats, which, as we have seen, are occasionally responsible for the transfer of the disease from place to place. While therefore not underrating these measures, which should form part of all methods of plague prevention, it is necessary to remember that although man is the agency by which the disease is conveyed from place to place, the rat is the means by which the disease, once imported into a given area, is afterwards disseminated throughout it. On this account I believe that the destruction of rats, combined with the other methods already indicated, will be completely successful in preventing outbreaks of plague in uninfected areas. In my opinion it is to the neglect of this factor of the rat that the failure of anti-plague measures in the past is to be largely attributed.

Any seaport in communication by shipping with an infected port is liable to infection. Here the principal danger lies in the disease being conveyed by infected rats rather than by human agency. Regulations on the following lines are, therefore, necessary and should be made obligatory: (1) all ships communicating directly or indirectly with infected ports should be periodically cleared of rats by the Clayton process or some similar method; (2) in addition other methods of destroying rats should be carried out, such as periodical poisoning or the permanent use of rat-traps, a certain number of which it should be obligatory on all ships to carry; and (3) inspections by the sanitary authorities of ports should be made from time to time to see that these measures are being carried out. To prevent the transfer of rats from the dock to the ship all gangways or other communications between the ship and the shore should be removed at night and a circular iron sheet having a diameter of three feet and a thickness of about a quarter of an inch should be affixed to each hawser or cable both near its attachment to the ship and also at its shoreward extremity. These "rat-shields" would effectually prevent any rats passing from the shore to the ship or *vice versâ*. They should be immediately put in place on coming into port on all occasions.

By the adoption of these measures all danger of infection from the side of the ship would be abolished except in so far as infected merchandise is concerned. Since it is by the inclusion of infected rats, or by infection derived from them, that merchandise usually becomes contaminated the destruction of these animals will materially reduce the danger of this taking place.

Similarly, to insure a condition of safety on shore it is essential that the destruction of rats in all ports liable to infection should be also carried out; and this is particularly necessary in the vicinity of all docks, wharves, and warehouses. Herein lies the necessity for a special plague department, for the work requires to be carried out systematically under careful supervision, such, for instance, as is now the case at Bombay and other places in India. Some central depôt in each town or city is necessary to which all rats captured may be taken for identification and if necessary bacteriological examination for plague bacilli. The question of species is important in view of the fact determined by Liston that the black rat (mus rattus) is by reason of its habits more concerned with the spread of plague than the brown rat (mus decumanus). The relative distribution of these two therefore becomes a matter of importance, but since they are both equally susceptible to the disease their extermination is necessary.

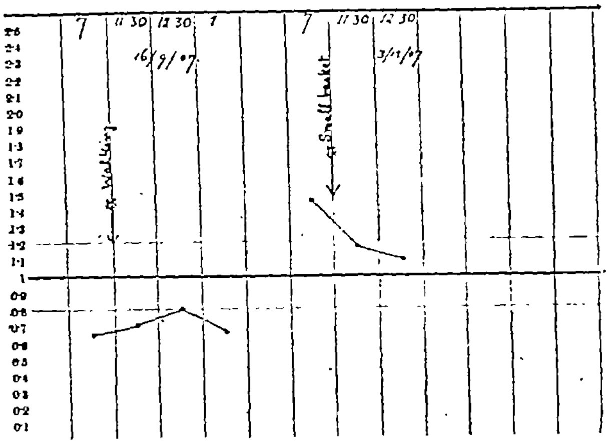
As regards the methods of combating the disease in an infected area reliance must not be placed on any one particular measure, for the greatest hope of success lies in the suitable combination of all methods. Thus the access of infected persons to uninfected areas should, where possible, be prevented. The destruction of rats should be carried out by the best means available, since there is good reason to believe that it is by means of chronic plague in the rat that the disease is carried over from one epidemic to another. It should be carried out in the "free season," and if poisoning is the means adopted it should be carried out just before the breeding season of the rat. On plague breaking out evacuation of infected houses should be immediately resorted to, but much harm will result if the inhabitants flee to uninfected areas; hence, where possible, arrangements should be made to accommodate them temporarily in the vicinity of their homes. Disinfection, except at the very commencement of an epidemic, is entirely useless, but for carrying it out at this time and also for dealing with imported cases a staff for disinfection purpose must be provided and, since the rat-flea is an important means of infection, they should be supplied with a solution such as phenol, which is both a pulicide probably the treatment consisted unintentionally of carefully graduated, artificially induced auto-inoculations. It was therefore decided to investigate the Frimley cases from this point of view and the following observations were made during a stay of one month at the sanatorium. In all, over 300 bloods were examined, from which a few cases only are selected under each heading for the sake of brevity.

The cases examined may be grouped as follows: (*a*) Cases which when examined at Brompton had a low index and which at Frimley with graduated work show a rise of the opsonic index.

CASE 1 (Chart 3).—The patient was a female, aged 18 years. Diagnosis, chronic pulmonary tuberculosis. Left upper lobe, rather quiescent second stage; left lower lobe, infiltration. Duration, nine months. Onset, insidious with cough. Sputum, tubercle bacilli present.

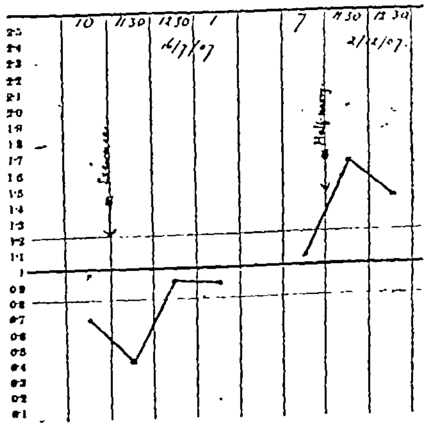
CASE 2 (Chart 4).—The patient was a male, aged 26 years. Diagnosis, infiltration of the right upper and lower lobes. Duration, 16 months. Onset, cough and hæmoptysis. Sputum, tubercle bacilli present.

CHART 4.



CASE 3 (Chart 5).—The patient was a male, aged 26 years. Diagnosis, infiltration of the right upper lobe. Duration, one year. Onset, cough followed by large hæmoptysis. Sputum, tubercle bacilli present.

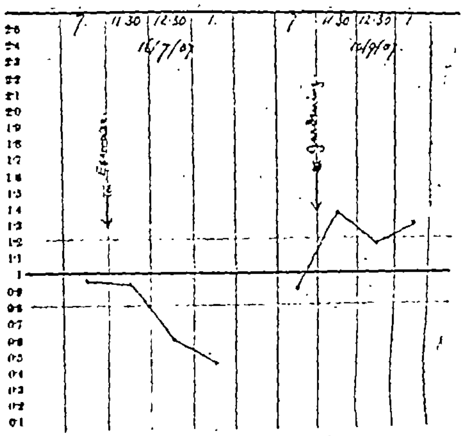
CHART 5.



CASE 4 (Chart 6).—The patient was a man, aged 23 years, a bookbinder. Diagnosis, chronic pulmonary tuberculosis. Extent, extensive infiltration of the left upper and left lower lobes; infiltration of the right upper lobe. Duration, 11 months. Onset, hæmoptysis. Sputum, tubercle bacilli present.

It might be argued that these high readings were not the result of auto-inoculation but merely of increased general physical fitness due to fresh air, &c., as obtained by sanatorium life. If a high index were merely evidence of a better resistance to the disease this might be so, but the high index expresses the fact that in the serum of the patient under observation there are substances which increase the phagocytic power of the white cells in excess of those contained in the blood of any healthy non-tuberculous subject. These substances are elaborated only in response to a defined stimulus, the introduction of bacteria or their products into the blood and lymph streams, and in these cases the only "tuberculin" used was that elaborated by the patient from himself and for himself. Thus we are dealing with examples of artificially induced auto-inoculation.

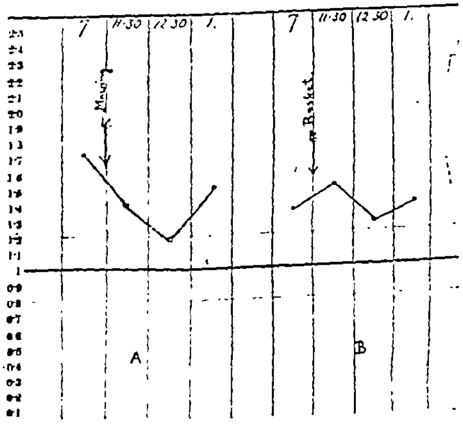
CHART 6.



(*b*) Investigations on cases working on the different grades of the labour scheme.

CASE 1 (Chart 7, A).—The patient was a male, aged 21 years, a clerk. Diagnosis, chronic pulmonary tuberculosis. Infiltration of the left upper lobe and apex of the lower lobe. Duration, seven months. Mode of onset, cough. Sputum, tubercle bacilli present. The patient is doing very well on full work. He has lost sputum and tubercle bacilli. The temperature is normal. He is now two stones over-weight.

CHART 7.



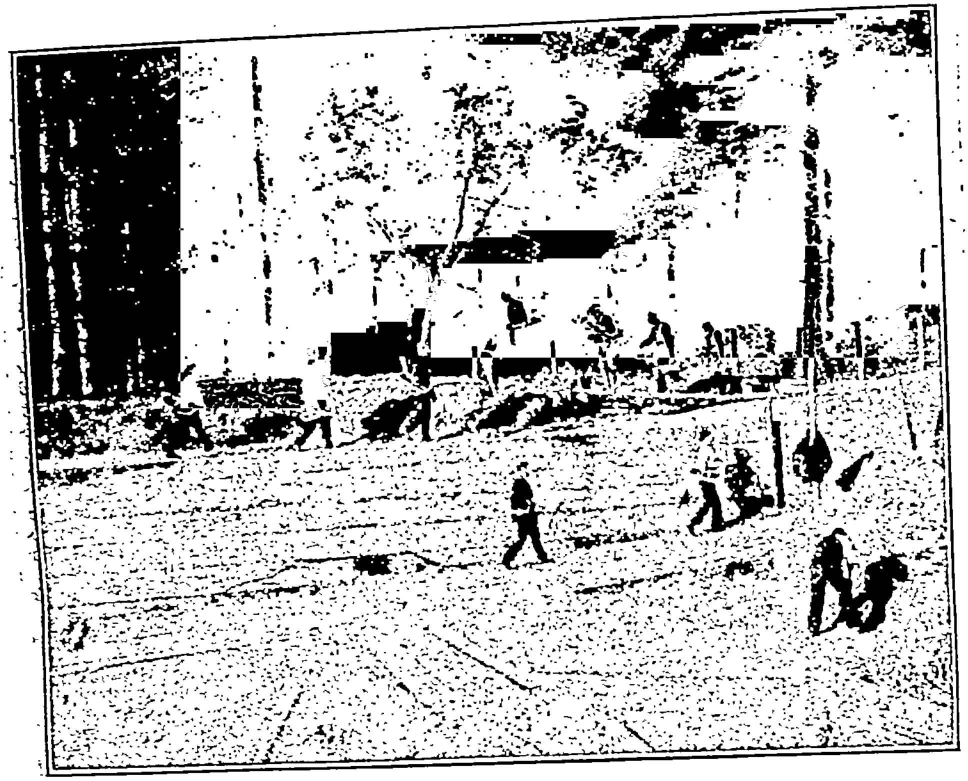
CASE 2 (Chart 7, B).—The patient was a male, aged 39 years, a carrier. Diagnosis, chronic pulmonary tuberculosis. Right lung, upper lobe, second stage early; lower lobe, first stage. Left lung, upper lobe, second stage early. Duration, two years. Onset, insidious (hæmoptysis +). Sputum, tubercle bacilli present. The patient is doing well on light work. The temperature is normal. Still expectoration with tubercle bacilli.

CASE 3 (Chart 8, A).—The patient was a male, aged 24 years, a general labourer. Diagnosis, chronic pulmonary tuberculosis. Extent, right upper lobe, excavation; left upper lobe, infiltration. Duration, three years. Onset, hæmoptysis. Sputum, tubercle bacilli present.

CASE 4 (Chart 8, B).—The patient was a male, aged 22 years, a blacksmith. Diagnosis, chronic pulmonary tuberculosis. Pleurisy left side. Infiltration of the left upper lobe. Duration, seven months. Onset, insidious (hæmoptysis +). Sputum, tubercle bacilli present.

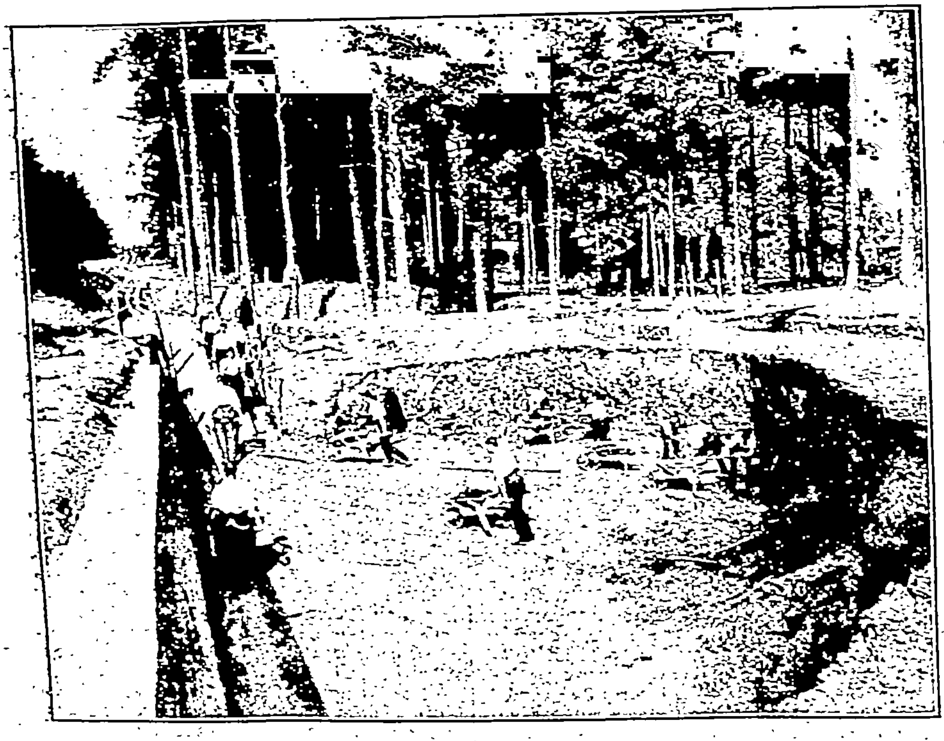
It was found that in 41 out of 43 cases the index was at some time of the day well above the normal, and, what is of even more importance, in no case did the exercise, even though severe, lower the index below the normal line—that is, the auto-inoculation was never so great as to produce a

FIG. 1.



Grade 1.—Basket work.

FIG. 2.

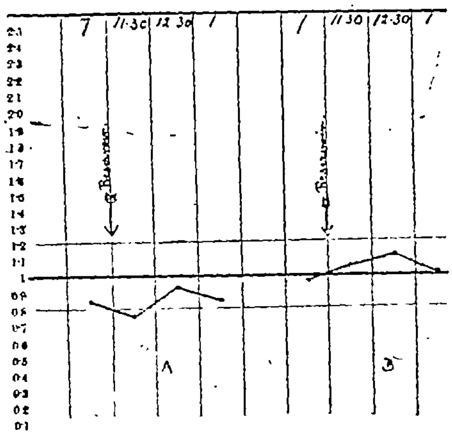


Grades 4 and 5.—Pickaxe and barrow work.

do hardest possible work. Temperature normal. Weight on discharge 10 stones 5 pounds. Lost expectoration and tubercle bacilli.

All these cases showed a return of the opsonic index to the normal, although the patient was doing the hardest of work. Therefore, the clinical opinion that the disease was arrested is confirmed by a precise scientific observation. These curves again negative the supposition that the high index noted in earlier stages might be due simply to increased general fitness of the body due to sanatorium life, since cases doing best of all and about to be discharged as showing "total arrest" gave an index no longer above the normal but within normal limits. The stimulus had been removed and the body was no longer called upon to elaborate protective substances; while if the high index in these cases had been caused solely by generally improved health it ought to have persisted so long as the robust health continued.

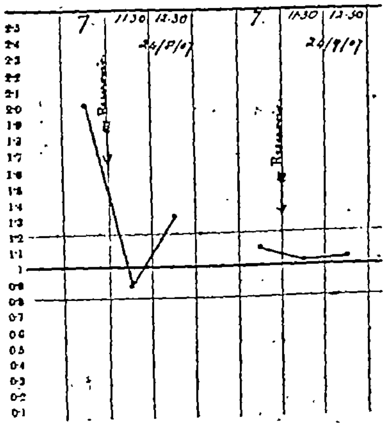
CHART 12.



Two cases may be added in which the progress from a high tuberculo-opsonic index produced by graduated artificially induced auto-inoculations to a normal index during the performance of the hardest work was actually observed.

CASE 1 (Chart 13).—The patient was a male, aged 26 years, a shop assistant. Diagnosis, chronic pulmonary tuberculosis. Extent, infiltration of the right upper lobe. Duration, three months. Onset, "influenza" and cough. Sputum, tubercle bacilli present. Highest known weight 10 stones 15 ounces. Able to do hardest work. The patient lost expectoration and tubercle bacilli. Temperature normal. Weight on discharge 10 stones 3 pounds.

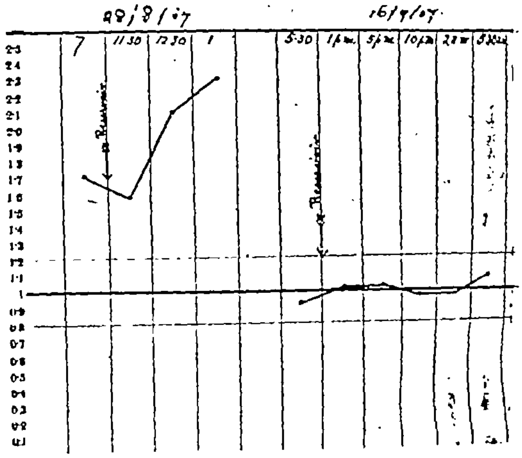
CHART 13.



CASE 2 (Chart 14).—The patient was a male, aged 32 years, a tin-worker. Diagnosis, chronic pulmonary tuberculosis. Extent: right upper lobe, infiltration; left upper lobe, infiltration. Duration, 11 months. Onset, pleurisy. Sputum, tubercle bacilli present.

(*d*) There are cases which give a normal index before and after the hardest exercise, and yet have not lost all expectoration or tubercle bacilli in the sputum. The patients were without fever, were apparently in robust health, were doing full navvy work, and showed physical signs of arrest, but in the early morning occasionally expectorated a little sputum which contained a few tubercle bacilli (two or three on a slide). (Cf. Dr. J. K. Fowler's case quoted in his book on "Diseases of the Lung," Fowler and Godlee, 1898, Ch. 34, p. 369).

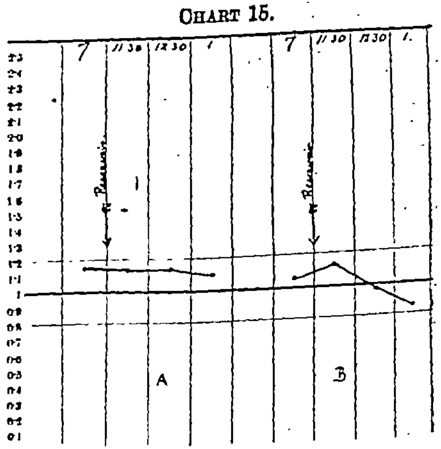
CHART 14.



CASE 1 (Chart 15, A).—The patient was a male, aged 39 years, a butler. Diagnosis, chronic pulmonary tuberculosis. Right lung: upper lobe, infiltration; lower lobe, infiltration. Left lung: upper lobe, infiltration. Duration, pleurisy four years before. Onset, cough six months. Sputum, tubercle bacilli present.

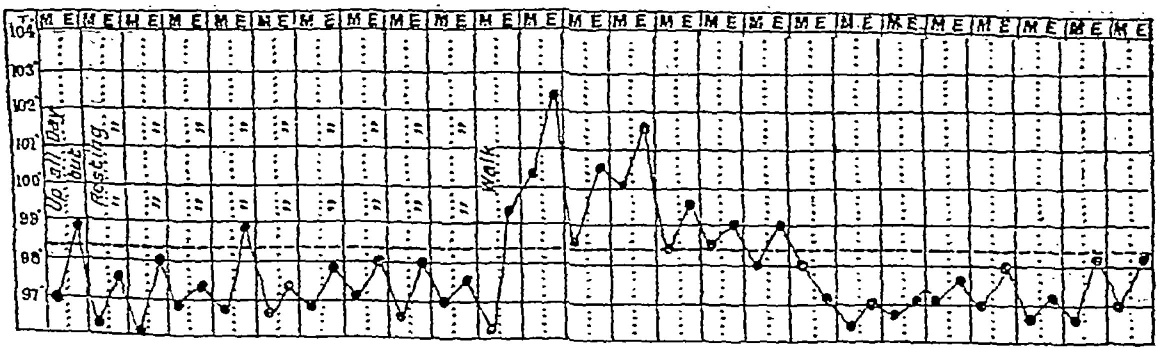
CASE 2 (Chart 15, B).—The patient was a man, aged 26 years, a compositor. Diagnosis, chronic pulmonary tuberculosis. Extent, infiltration of the left upper and lower lobes. Duration, 16 months. Onset, hæmoptysis. Sputum, tubercle bacilli present. Highest known weight, 7 stones 7 pounds. The patient was able to do hard work. Moist sounds in the lung disappeared. Temperature normal. Weight on discharge, 8 stones 2 pounds 12 ounces. Scanty expectoration in the early morning which still contained tubercle bacilli.

CHART 15.



The practical outcome of these investigations is this. The labour scheme so ably devised and carried out by Dr. Paterson has been submitted to a new scientific test by means of which its effect on the blood of the patients has been traced. The opsonic index has shown that the exercise has supplied the stimulus needed to induce artificial auto-inoculation, and that its systematic graduation has regulated this in point of time and amount. This coöperation with the natural efforts of the blood has enabled Dr. Paterson to send his patients back to their accustomed work, however hard it may be. But the investigation has done more than explain a successful mode of treatment. Dr. Paterson agrees with me that with the aid of the opsonic index he can regulate the stimulus with scientific accuracy and obtain his results more certainly and more rapidly. This, of course, involves work in the laboratory. But it also means a more rapid and a more certain discharge of the three or four lobes with fibrosis—a temperature of 99° has not the same significance, but it is still regarded as a danger signal and the patient is specially watched. A temperature of 99·6° in women appears to correspond with the temperature of 99° in men. It is necessary to emphasise the importance of the significance of a temperature of 99°. If this degree of fever is observed and the patient is ordered to rest for a few days no harm will result, but if it is disregarded and the patient continues to work he will, later, in addition to the headache, complain of pains in his joints and limbs, a condition very closely resembling influenza. Indeed, this result of over-exertion is often called influenza. Should the patient still continue to work or should he have against orders very much over-exerted himself the temperature will rise to 100° or over and pleurisy may develop. This complication seems to be the invariable result of excessive work or overlooking the danger signal—i.e., the temperature of 99°.

The following facts are significant. During the first year that the sanatorium was opened the patients were allowed to play games, such as croquet, quoits, &c., in the evenings and on Saturday afternoons, but it was soon found that many patients in this way took too much exercise. Their improvement was not satisfactory, as they were apt to get too keen over the games and to forget that they were under treatment. *A rule was therefore made that patients were not to play any* games, such as croquet, until they had reached the stage of basket work. Much better results followed its adoption. The reason is obvious: a patient walking his prescribed four miles a day is having sufficient exercise, but if he plays a game of croquet in addition he has too much. It was therefore established, and it is a fact of the utmost importance, that the hours of recreation must be regulated with just as much care as the hours of work. The accompanying chart shows the effect produced by an act of indiscretion upon the temperature of a patient who should have been resting all day. It occurred upon a certain summer evening when, as he considered himself to be free from control, not having realised that he was always under treatment, he went for a short walk of about half a mile. Playing the piano or singing must be regarded as exercise, as I have known a musical patient after an hour at the piano experience a rise of temperature to 99°, with headache and general malaise.



After the sanatorium had been opened about 18 months and further experience had been gained I came to the conclusion that the patients who had a slight rise of temperature (99°) as a result of over-work, and for whom in consequence rest for a few days had been prescribed, were not infrequently not only none the worse for this sequence of events but rather the better. Some patients even appeared to date the commencement of their improvement from the period of rest following over-work. It was accordingly decided to be unnecessary to put these patients back to the earliest grade of work and they were permitted, after a few days' walking exercise, to recommence work in the grade reached when they suffered from over-exertion. This practice has been continued ever since with satisfactory results but it is impossible to lay too much emphasis on the fact that such patients require to be watched with especial care as regards loss of appetite, the presence of *headache*, or of a rise of temperature. In the course of my earlier experience I observed cases of another type—i.e., patients who from the indications given by the temperature, appetite, and demeanour, ought to have been doing well but who remained in a stationary condition, and were in fact only "marking time." It was doubtful whether such patients should be given harder work or more rest. They were considerably under the normal weight and their general state did not suggest a capacity to undergo an increase of labour. After careful consideration it was determined to try the effect of harder work with a view to improving the appetite. I am glad to state that all such patients have shown progressive improvement on being given work of a higher grade.

The diet is liberal and consists of the ordinary food which the working-classes provide for themselves when they are in a position to afford it. The patients have three meals in the day. Breakfast consists of bacon, &c.; dinner consists of meat and suet or milk puddings; and supper consists of soup, oat cakes, Cornish pasties, or cheese, &c. For the first 16 months the patients used to have three pints of milk and an egg every day; now they only have milk in their tea, coffee, and puddings, and they are not given an egg every day, but they do just as well on this as on the more stereotyped and conventional form of diet and do not become excessively corpulent. Of course, patients who are very emaciated have milk if it is thought necessary, but as a routine milk is not used except as it would be in their own homes. The standard aimed at as regards nutrition is to raise the patient's weight to a few pounds above his highest known weight or to a few pounds above the normal weight for his height. Patients who tend to become excessively fat have their diet reduced in quantity.

Medicines such as cod-liver oil, malt, &c., are not used. Practically the only drugs prescribed are aperients.

The following work which has already been accomplished will show the scope and variety of the tasks which the patients have performed. About 900 tons of mould, sand, and gravel have been carried in baskets an average distance of 200 yards. The whole establishment has been kept in firewood; it has not been necessary to obtain any from outside sources. The boots of the patients and staff have been kept in repair. The patients' block of buildings has been painted. The whole of the grounds has been kept in order. In addition to these occupations the patients have been engaged in mixing and laying 1000 tons of concrete and in excavating and moving to a distance of 300 feet 5000 tons of sand in the construction of a reservoir. The reservoir is 108 feet long, 54 feet wide, and 12 feet deep; and the walls are 4 feet thick at the base and 1½ feet at the top. In addition 3½ acres of land have been trenched, cleared, and brought into cultivation.

In order to ascertain the results of the system of graduated labour, all patients on their discharge have been requested to keep the administration informed as to their progress.

In considering the following results of the treatment of pulmonary tuberculosis by graduated labour it is to be distinctly understood that I have only quoted the cases of patients who went through all the grades and eventually performed the highest work. Furthermore, all these individuals were patients who were discharged during the years 1905 and 1906, so that the statistics refer to patients who have been at work for from one to two and a half years. Of the abovementioned patients the number discharged during 1905 and 1906 was 164. Of these 119 had tubercle bacilli in their sputum; four had physical signs and gave a tuberculin reaction; one had definite signs, but the sputum was not examined; 31 had definite physical signs, definite histories and definite symptoms of pulmonary tuberculosis but no tubercle bacilli were found in their sputum when it was examined at the sanatorium; and nine had histories and symptoms of pulmonary tuberculosis but no physical signs and no bacilli were found in the sputum, nor were they bodies represent a stage in the life cycle of the protozoan organisms described by Dr. Henry Wade and myself as occurring in certain carcinomatous tumours. We had previously observed such rods in the old silver-gold preparations but never in large numbers, and we were unable to attach any significance to them. In sections prepared by the improved ammonia-silver process and decolourised by cyanide these rod-shaped bodies tend to retain the black deposit for a short period subsequent to their development; at a later stage they are much more readily bleached by the cyanide. These preparations reveal in the protoplasm of many of the epithelial cells, especially in carcinatoma of the breast, more or less numerous spherical or oval bodies which were described in previous papers, and from these bodies the rods can be seen to originate. In palladium methyl violet preparations these globular bodies can also be recognised, often appearing distinctly nucleated, and various stages in their transformation into rods can easily be observed. The evidence of the histological preparations upon this point is confirmed by that derived from an agar culture from a secondarily infected gland in a case of malignant adenoma of the intestine, described by Dr. Wade and myself. This culture contains in the substance of the agar numerous spherical bodies with the staining reactions of those demonstrable in the protoplasm of some carcinoma cells, and the study of preparations of this culture stained by the methyl violet method has revealed the fact that these spheres become transformed into rod-like bodies identical with those that can be seen in the tissues. In a future paper I hope to deal fully with the subject of the life cycle of these protozoan organisms. If these rods represent merely a single phase in a complicated life cycle, it should be easy to understand how in many carcinomatous tumours they can be found only in small numbers whilst in other tumours of the same kind they are abundant. It seems to me probable from evidence collected that not one species of protozoan organism but several closely allied species are the pathogenic agents in the production of carcinomatous tumours. It at least appears that the forms found in carcinoma of the breast present certain characters which distinguish them from those that may be observed in squamous epitheliomata and in intestinal tumours, although the life cycles are essentially the same.

I have endeavoured to ascertain what becomes of the rods, but as yet only a few facts have come to light. At first it seemed probable that these bodies are motile forms which escape from the cell in which they have originated and which, after travelling some distance, infect other cells, but this hypothesis on being tested has failed to obtain any confirmation. The evidence, indeed, very strongly supports the view that the rods, instead of tending to escape from the cell, seek to penetrate the nuclear membrane and that they undergo a further evolution within the substance of the nucleus. Not only may the rods frequently be seen to abut upon the nuclear membrane, but they may sometimes be observed to have partially penetrated it, either by movement or by means of end-growth. The occurrence of characteristic rods wholly within a nucleus is quite common and occasionally several may be seen in one nucleus.

In conclusion, I would say that if pathologists will apply the palladium methyl violet method to a few properly fixed and somewhat recently obtained carcinomata of the breast and squamous epitheliomata, I am confident that they will quickly be able to confirm and to extend these observations which I have here briefly recorded. I have to express my indebtedness to Mr. F. M. Caird, Mr. David Wallace, and Dr. M. B. Hannay for most of the tissues used in these investigations.

APPENDIX.

The palladium methyl violet method.—The reagents required are saturated solution of palladium chloride in 1 per cent. citric acid in water, 1 per cent. solution of methyl violet 6 B or 5 B, saturated solution of iodine in 2·5 per cent. potassium iodide, equal parts of turpentine and benzole, equal parts of pure anhydrous aniline oil and benzole, benzole and benzole balsam. The tissues should be fixed in 5 per cent. formalin in ¾ per cent. salt solution (and preserved in the same fluid or in alcohol), or for 24 hours in Heidenhain's sublimate solution, with subsequent removal of the mercury by means of iodine in the usual way. Cut thin sections by the dextrine freezing method. Place the sections overnight in the palladium solution. Wash them in three changes of water and then place them for from 10 to 20 minutes in the methyl violet stain. Wash the sections shortly in water and transfer them to the iodine solution, in which they should remain for from 10 to 20 minutes. Next transfer the sections to a bowl of water. In this they may be left for an hour or longer without suffering harm. Steel needles must not be used in these operations. Take a section up from the water upon a perfectly clean slide. Carefully remove water from around it by means of a towel. Next lay the slide upon the table and with a piece of smooth blotting or filter paper (folded double) blot the section in the same manner as one dries a sheet of wet manuscript. Immediately afterwards, without allowing it to dry completely in air, pour over the section some drops of a mixture of equal parts of turpentine and benzole. Renew this turpentine-benzole after a few seconds and then place the slide upon the heater (described below), where it must remain at a temperature of about 60° C. until completely dehydrated. If the turpentine-benzole tends to evaporate off the section add more by means of a pipette. When dehydration is complete the previously black and opaque tissue assumes a dark blue and faintly translucent appearance. Generally from 15 to 20 minutes are required. When the section seems dehydrated remove the slide from the heater, allow it to cool, and then pour off the turpentine-benzole. Decolourise with aniline-benzole. Renew this two or three times. Avoid breathing on the slide as the smallest trace of moisture in the aniline-benzole will cause complete decolourisation of the section. When the dye ceases to come away wash the section in several changes of pure benzole and mount in balsam in benzole. It is essential that the section should be completely dehydrated on the heater. Any spot in which moisture has been allowed to remain will be decolourised by the aniline-benzole. A heating apparatus of a very simple form is sufficient for the purposes of this method. I use a small spirit lamp placed below a tripod stand, on the top of which there is a thin metal plate, and upon this again two small iron bars laid parallel to each other and at such a distance as just to allow the two ends of a microscopic slide to rest upon them. By such an arrangement heat is transmitted only by the two ends of the slide and the turpentine benzole is driven to the centre. Tissues that have been in alcohol or in formalin for over two years do not, as a rule, stain deeply enough, and must then be regarded as unsuitable for the application of this method.

ON THE RELATIONSHIP OF CANCER CELLS TO THE DEVELOPMENT OF CANCER.

BY J. E. SALVIN-MOORE, A.R.C.S., F.L.S., F.Z.S.,
PROFESSOR OF EXPERIMENTAL AND PATHOLOGICAL CYTOLOGY AND
DIRECTOR OF THE CANCER RESEARCH LABORATORIES,
UNIVERSITY OF LIVERPOOL;

AND

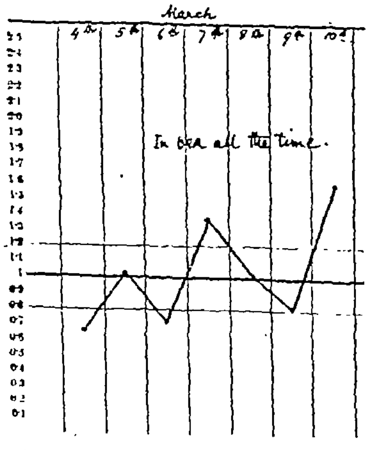
C. E. WALKER,
ASSISTANT DIRECTOR OF THE CANCER RESEARCH LABORATORIES,
UNIVERSITY OF LIVERPOOL; AND HONORARY LECTURER
IN CYTOLOGY IN THE LIVERPOOL SCHOOL OF
TROPICAL MEDICINE.

IN the present communication we wish to record some observations made in the Cancer Research Laboratories, University of Liverpool. The observations in question relate to the propagation of cancer in mice. The tumours utilised are derived from a growth originating sporadically in a mouse, and most generously placed at the disposal of the Liverpool Cancer Research Committee by Professor Ehrlich of Berlin. The tumours upon which these observations have been made are of exceptional virulence. They are graftable from one mouse to another—that is to say, if small fragments of the growth be removed from an animal these fragments will grow when placed under the skin of a healthy individual. So far as can be ascertained from purely cytological examination of the process, the new tumour in inoculated mice appears to proceed directly from the cells belonging to the original tumour which have been mechanically transferred. The grafted tumour, in fact, apparently arises from the implanted cells, and not through any alteration of the tissues of the new host which surround the graft.

For purposes of investigation portions of these tumours were removed from mice and subjected for periods of from constituents of the experiment were satisfactory. In the case of the normal serum, an attempt was always made to obtain an average count of one bacillus per cell—i.e., an average of about 100 bacilli in 100 cells. In all experiments 100 polymorphonuclear cells were counted. The films were stained as follows: 1. Fixed in a saturated solution of hydrargyrum perchloridum, one quarter of a minute. 2. Stained with Ziehl's carbol-fuchsin, warm, one minute. 3. Decolourised with sulphuric acid 2½ per cent. 4. The red cells were decolourised with acetic acid, 4 per cent. 5. Counterstained with aqueous methylene blue, 1 per cent. With a view to eliminating as far as possible the personal element and to prevent the possibility of a biased mind influencing the results all experiments were made with unknown bloods. That is to say, after the bloods to be examined had been drawn each blood-tube, bearing the name of the patient, was handed over to the assistant who rubbed out the names and replaced them with numbers, in any order he liked, and kept this key to the bloods himself. The indices were then worked out by experiment before seeing the key, and afterwards the curves exhibited in this paper were constructed. *Thus in no cases during the experiment was it known which blood was being examined.* It was found in practice that when examining day after day a number of such unknown bloods, several samples of the blood of a single healthy individual mixed with other bloods showed indices which varied rather over one decimal place on either side of unity. Further, it has been determined by Bulloch and others that the bloods of presumably healthy individuals present opsonic indices varying between 0·8 and 1·2 on either side of unity. It was therefore decided to regard all indices within these limits as normal.

Before considering the effect of exercise upon the opsonic index in pulmonary tuberculosis it must be mentioned that in active disease spontaneous auto-inoculations are continually taking place even though the patient be at rest. Such patients, as Wright has expressed it, are living in "a succession of negative and positive phases." Chart 1 is an example of this. Further, it must be remembered that the degree of auto-inoculation is in proportion to the activity of the disease. There are cases, indeed, in which auto-inoculations cease when the patient is at rest but reappear after any movements sufficient to affect the focus of infection. In all charts which follow the first index was taken before the patient had got out of bed in the morning, the second was taken immediately after exercise, and the third and fourth during a subsequent rest of from one and a half to two hours' duration. Chart 2A graphically represents the effect of exercise on the opsonic index in cases of early pulmonary tuberculosis, Chart 2B the absence of variation in healthy persons.

CHART 1.



Wright points out when comparing the respective advantages of artificially induced auto-inoculations and inoculations of bacterial vaccines as means of treatment in bacterial infections that if the former method is adopted unmeasured doses of a living culture are being used, and therefore the method can never be entirely dissociated from risk. Now at the Brompton Hospital Sanatorium at Frimley during the past two and a half years the patients during their stay have been treated by gradually increasing amounts of work, the last grade being full navvy work, almost as severe as it is possible for even a healthy individual to accomplish. In spite of the greatest difficulties Dr. M. S. Paterson, the medical superintendent, has evolved a scheme of very carefully graduated work-exercise, beginning with gentle walking and ending with concrete-making, excavation work, &c. This has been accomplished with tuberculous patients, many of them showing extensive signs of disease in the chest, with expectoration containing tubercle bacilli, but without fever. The treatment has been remarkably successful. It has only been possible to accomplish this (1) by instituting the most careful graduation of the exercise; and (2) by close observation of the temperature chart, work being at once stopped when fever appears. It follows from what has gone before that the work-exercise scheme at Frimley must be associated with auto-inoculation and at

CHART 2A.

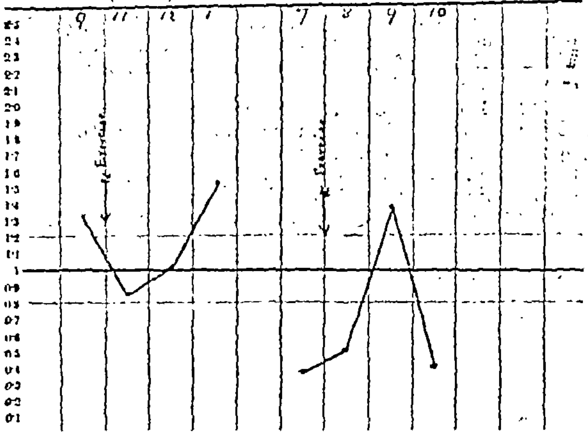


CHART 2B.

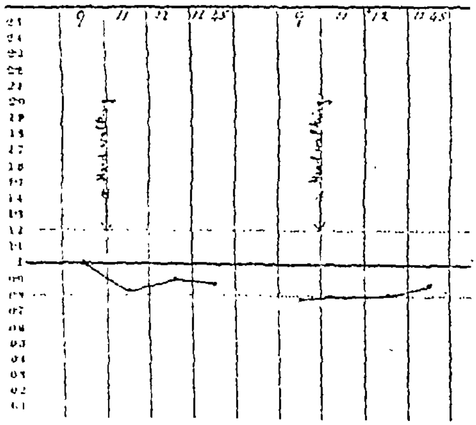

CHART 3.

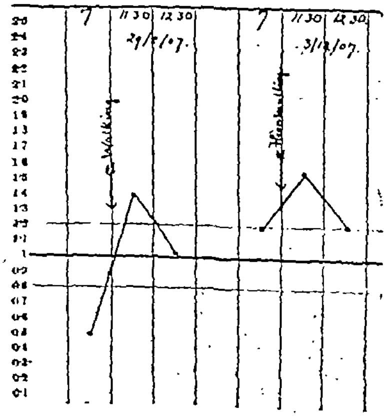

such an action; nor is this disproved by the recent and important experiments of Payr. He transplants one lobe from the neck of a dog into its spleen; by a later operation he excises the lobe remaining in the neck—this produces no ill-effect; and by a third operation he removes the spleen with the transplanted thyroid lobe in it—this is followed by the death of the dog. By the aid of the experience gained in these experiments Payr performed an important operation on the human subject. He had under his care a cretinous child, aged six and a half years. The child had been treated by thyroid feeding almost without result. Payr excised part of the thyroid of the child's mother and planted it in the spleen of the child, with the result that the child was greatly improved.

Notwithstanding the foregoing objections it may well be that the enlarged thyroid of Graves's disease does yield an excessive secretion, that this is injurious to the economy, and that these ill-effects may be relieved by the administration of the milk of thyroidless goats, a treatment suggested and practised by Lanz. To this treatment it may be objected that even if the blood serum of the goat contains an antidote this would not pass into the milk, which is a secretion and not a transudate. In this connexion it may be pointed out that if after total thyroidectomy in the dog the removed lobes are simply dropped back into the wound before it is closed the symptoms resulting will be altered; the dog will die, but it will live a few days longer than it otherwise would and it will not have the tremors, paralysis, and convulsions which usually follow the operation, but will die from asthenia. This difference is presumably caused by the absorption of the replaced lobes.

Following these lines I removed from three cats the thyroid gland and fed the cats on ordinary cow's milk. Two of these cats died with the usual symptoms, tremors and paralysis, in four and five days; the third died from asthenia in 15 days. In three other cats the same operation was performed and they were fed subsequently on the milk of a thyroidectomised goat. None of the three had tremors or paralysis; they died from asthenia in 9, 12, and 14 days. The fact that not one of these three cats had the usual symptoms certainly suggests that the goat's milk contained some special constituent.

In a disease like Graves's, in which many of the cases greatly improve under any reasonable treatment, it is not easy to say with confidence that any particular remedy has done good. However, there are several cases on record in which the milk treatment of Lanz seems almost certainly to have been of benefit. Thus Lanz himself gives one case so severe that from his previous experience he expected the patient to die who yet made a good recovery. Other satisfactory cases have been recorded on the continent and one in America.

The first case at the Prince of Wales's Hospital treated in this way was that of a young woman, aged 23 years, under the care of Dr. R. Murray Leslie, to whom I am indebted for permission to refer to the case. The patient was first admitted in August, 1906. She came with a history of having had a month or two previously an attack of rheumatic fever. On admission she was suffering from palpitation, with a pulse of 120, slight prominence of the eyes, and a soft pulsating goitre which gave a blowing sound on auscultation. She improved under rest and medical treatment and went out on Oct. 22nd. Her weight at this time was 7 stones 5 pounds. After her return home she became worse and was readmitted to the hospital on Jan. 3rd, 1907. Her weight was now 6 stones 10 pounds. She had marked exophthalmos so severe that she could not completely close her eyes. The thyroid gland was greatly enlarged with a loud systolic murmur over it; there was also a systolic murmur at the heart's apex. The pulse was 120. There were marked tremors of the hands. The patient was at first placed on the same treatment as she had done well on before. After a few days she was ordered rodagen, which she took for one month without any benefit. Her weight was now 6 stones 9 pounds. She was then put back on her former medicine and also had some applications of the x rays to the goitre. She did not improve, but lost flesh considerably, her weight on March 26th being 5 stones 12 pounds. She was now given the milk of a thyroidectomised goat, taking for some time the whole of the milk which the goat gave. The patient now gradually and markedly improved. Her weight steadily went up; on May 7th it was 6 stones 11 pounds and on June 18th (shortly before she left) it was 7 stones 1½ pounds. Besides this she felt, and obviously was, much better and stronger; the goitre and exophthalmos were somewhat less and the pulse-rate was about 105.

The second case was not in the hospital but occurred in the practice of a medical friend. The patient, a married woman, aged 48 years, was first seen in April, 1907. She complained of palpitation, of feeling weak, and of loss of flesh. Her weight, formerly 11 stones, was now 9 stones. The eyeballs were prominent and there was slight thyroid enlargement. The pulse was 120. She was treated with bromide, belladonna, digitalis, and arsenic without any good result. On June 18th she was kept in bed and Leiter's tubes were applied to the goitre. The pulse was 120. On July 9th she began to take milk from thyroidectomised goats. She gradually improved. On the 26th she began to get up. On August 17th the pulse was 84. On Oct. 17th she had continued to improve, her weight was 8 stones 4½ pounds, and the pulse was 80. She was still taking a small quantity of the milk (the yield of the goats was at this time diminishing). On Dec. 14th her weight was 8 stones 12 pounds and the pulse was 84. She ate and slept well. There was very little palpitation. She could do a little light household work. While taking the milk the only medicine given was bicarbonate of sodium and gentian.

A third case was also under the private care of a friend. The patient was a woman, aged 28 years. About nine years ago she developed unilateral proptosis without any other symptom. She had had two severe attacks of influenza, the last two years ago. After the second attack she had a cerebral seizure, falling and becoming momentarily unconscious. This was followed for a time by convulsive movements of the left arm, which were worse during sleep; this slowly passed off. About a year ago the patient one night felt a pain in her throat and on putting her hand up to her neck found a swelling which proved to be a goitre. After this the second eye became also prominent. Besides this she had slight choking attacks at night and was very restless in her sleep. She was treated for several weeks with drachm doses of rodagen twice a day; this did not produce the slightest improvement. On July 25th she commenced taking about one and a half pints of the milk of a thyroidectomised goat a day. There has been no material change in the pulse-rate, which has usually been under 100, or in the weight, which has been fairly steady at about 8 stones 12 pounds. But there has been considerable improvement in her general condition, as shown by her subjective sensations and the observations of her friends; also the attacks of palpitation to which she was subject have become less frequent. The exophthalmos, which was throughout slight, has not altered.

There is no great difficulty in carrying out this treatment, especially in the country. Goats take ether well; the thyroid gland in them consists of two separate lobes lying one on each side of the trachea; there is no isthmus. As far as my experience goes it is best to choose an animal two or three years old and to operate about three or four weeks after kidding. Goats as a rule have their young in the spring.

That others may be induced to try this treatment this year is my reason for what I fear may seem to be a premature publication of results.

Devonshire-place, W.

A CASE OF ACUTE SUPPURATION IN A THYROID ADENOMA DUE TO THE BACILLUS TYPHOSUS.

BY F. G. MELANDRI, M.D. BOLOGNA,
PHYSICIAN TO THE ITALIAN HOSPITAL, QUEEN-SQUARE, LONDON;
AND
T. P. LEGG, M.S. LOND., F.R.C.S. ENG.,
ASSISTANT SURGEON TO THE ROYAL FREE HOSPITAL, GRAY'S INN ROAD, LONDON, AND TO THE ITALIAN HOSPITAL.

THE patient, an Italian, aged 26 years, was admitted to the Italian Hospital on April 13th, 1907. His illness dated from four days previously. His pulse-rate was 116, the respirations were 36 per minute, and there were signs in the chest of acute pneumonia. On the 21st, the twelfth day of illness, the temperature came down to normal but the negative phase and therefore never in excess. It was observed during these investigations that in some bloods examined tuberculo agglutinins appeared in association with the immune tuberculo-opsonins. This must be taken as another evidence of an immunising response on the part of the organism. When the difficulties of such a method of treatment and the danger of the weapon employed are taken into consideration it will be readily understood that every now and then, in spite of the most careful supervision, an excessive auto-inoculation must take place. Such an over-dose is readily recognised clinically. A patient previously doing well on the grade of work prescribed for him and with no abnormality of temperature suddenly complains of feeling tired, of loss of appetite and of headache, and the temperature chart registers an elevation to 99° or 100° F. These are precisely the symptoms which are found during the negative phase after an excessive dose of bacterial vaccine. Owing to the extreme care and judgment exercised by Dr. Paterson in the selection of suitable work for the patients and to the rigid supervision carried out, not only during work hours but throughout the day, these over-doses are very infrequent at Frimley. During my stay of one month at the sanatorium only two transient instances of such over-dosage occurred, and in both cases the opportunities were taken to examine the bloods (Charts 9 and 10). In both cases then the febrile rise and other symptoms coincided with a negative phase; and while in both cases a positive phase appeared afterwards, in the first the recovery was simultaneous with the decline of the fever. It should be noted that this patient was kept in bed, while the other was allowed to do modified work during his pyrexia.

CHART 8.

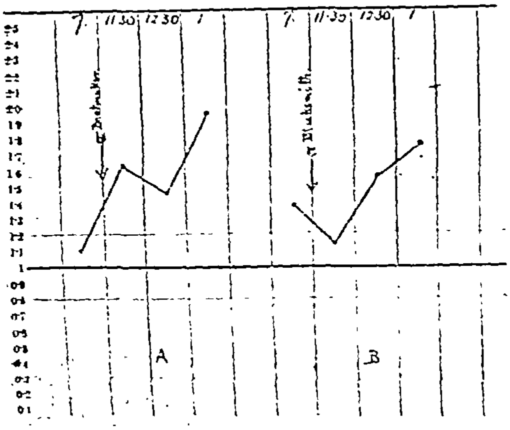

CHART 9.

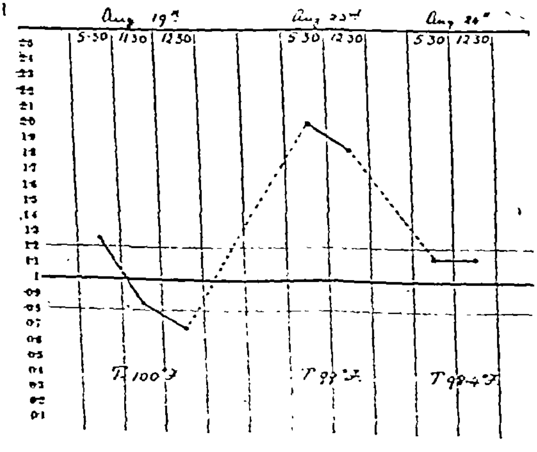
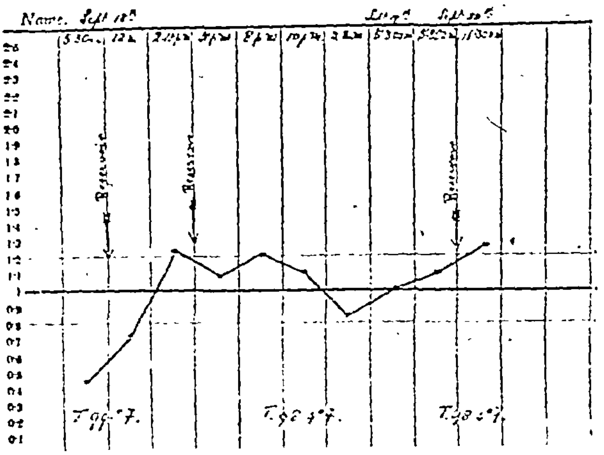


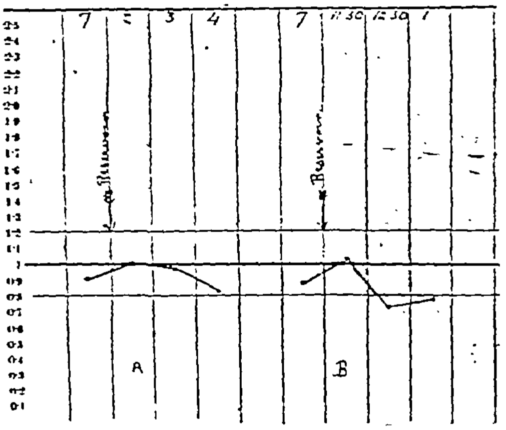
(c) If a focus of infection becomes arrested auto-inoculations from this focus cease. In Wright's words: "Where an artificial inoculation can no longer be induced in a focus which previously could be influenced we are entitled to conclude that the focus of infection is extinct." Therefore, some of the early cases of pulmonary tuberculosis, many of whom had lost expectoration and tubercle bacilli, who were doing the hardest possible work without rise of temperature or discomfort, might be expected to afford evidence in their blood that their focus of infection was no longer aglow but arrested. The following results were obtained from patients constructing a water reservoir (full navvy work).

CHART 10.



CASE 1 (Chart 11, A).—The patient was a male, aged 24 years, a brass finisher. Diagnosis, chronic pulmonary tuberculosis. Infiltration and fibrosis of the right upper lobe. Duration, 18 months. Mode of onset, hæmoptysis. Sputum, tubercle bacilli present. Highest known weight, 12 stones 2 pounds. The patient was able to do full work; lost sputum and tubercle bacilli. The temperature was normal. The weight on discharge was 12 stones 10 pounds.

CHART 11.

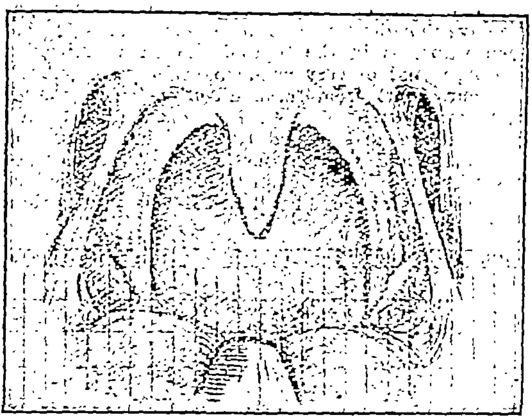


CASE 2 (Chart 11, B).—The patient was a male, aged 23 years, a warehouse salesman. Diagnosis, early pulmonary tuberculosis. Extent, infiltration of the left upper lobe. Duration, three months. Highest known weight, 9 stones 10 pounds. Onset, insidious (hæmoptysis +). Sputum, tubercle bacilli present. The patient was able to do hardest work. Temperature normal. Weight on discharge 9 stones 12 pounds. He lost expectoration and tubercle bacilli, though slight cough persisted.

CASE 3 (Chart 12, A).—The patient was a male, aged 26 years, clerk. Diagnosis, chronic pulmonary tuberculosis. Extent, right upper lobe, infiltration; left upper lobe, infiltration. Duration, nine months. Onset, hæmoptysis. Sputum, tubercle bacilli present. The patient was able to do hardest work. Temperature occasionally 99° F. Weight on discharge, 10 stones 12 pounds. Lost cough, expectoration, and tubercle bacilli.

CASE 4 (Chart 12, B).—The patient was a male, aged 25 years, an iron-moulder. Diagnosis, chronic pulmonary tuberculosis. Extent, infiltration and fibrosis of the right upper lobe. Duration, 12 months. Onset, pleurisy (nine years ago). Sputum, tubercle bacilli present. Highest known weight, 9 stones 12 pounds. The patient was able to fenestra on each side, while the palato-pharyngeus forms the inner boundary of a third web of mucous membrane.

The patient, a male, aged 18½ years, had never suffered from sore-throat since he was two years old, at which time he had scarlet fever with a "bad throat." When I saw him there were no symptoms whatever, and the voice did not appear to be modified in any way. There was no other defect observable in the throat, nose, eye, or ear.



A possible explanation of these fenestrations is that the condition of the anterior faucial pillar was similar to that shown in the posterior pillar until scarlatinal angina caused the thin web of mucous membrane to ulcerate, leaving the strands of palato-glossus muscle seen in later life.

The illustration has been drawn with great care and I think that it very accurately represents the existing conditions. A similar case was illustrated by Fullerton,[1] who refers to other recorded instances.

Description of the illustration.—The anterior pillars of the fauces which contracted well on stimulation and on phonation are seen to be strands of muscle fibre passing down to join the tongue and are covered with normal mucous membrane, forming the inner boundary of a fenestra on either side.

The posterior pillars show indication of a separate bundle of muscle united to the lateral pharyngeal walls by thin mucous membrane. The tonsils are small but lie between the anterior and posterior pillars, and small remains of the plica tonsillaris are present. A small mass of adenoid tissue lies behind the left posterior faucial pillar.

Bristol.

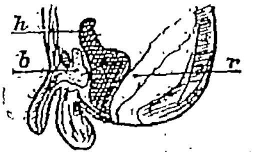
NOTE ON A CASE OF HYDATID CYST IN THE PELVIC CAVITY.

By P. Clennell Fenwick, M.B. Lond., F.R.C.S. Edin.,

HONORARY SURGEON TO CHRISTCHURCH HOSPITAL, NEW ZEALAND.

HYDATID disease is so frequently seen in this colony that little notice is taken of its occurrence in the lung, liver, or brain. I have recently had a case of a cyst almost filling the pelvic cavity and causing partial retention of urine which may be of interest to surgeons who specialise in urinary disease.

The patient, a man, aged 27 years, was admitted into Christchurch Hospital complaining of pain in the lower part of the abdomen and difficulty in passing urine. He stated that for the last seven years he had had attacks of pain in the right iliac fossa, but during the last three weeks the pain had occurred all over the abdomen. The pain ran down into the right testicle and was severe enough to make him perspire profusely. Micturition was normal except when he had held urine for longer than usual, and then he found that he could not begin the act. The urine was normal. Per rectum a large hard swelling was felt extending up the rectum on the anterior aspect. The swelling was adherent to the rectum. Anteriorly there was a large firm swelling of the size of an orange situated to the left of the middle line reaching from the pubes to within one inch of the umbilicus. It was fixed and did not fluctuate.



h, Hydatid. *b*, Bladder. *r*, Rectum.

I opened the abdomen in the middle line below the umbilicus and immediately exposed the tumour. The apex was a small knob of the size of a walnut. On examining further the mass could be traced downward into the pelvis and was found closely adherent to the rectum. There was no adhesion to the bladder. I passed a needle into the apex of the tumour and drew off hydatid fluid. The tumour was then opened and a great quantity of large and small cysts were evacuated. When filled with fluid from the douche the empty sac held 250 grammes. I drained the sac and fixed it to the abdominal wall.

The patient has had no difficulty in micturition and has now left the hospital in good health.

Christchurch, N.Z.

NOTE ON A CASE OF TUBERCULOSIS OF THE TESTIS ILLUSTRATING AN UNUSUAL ABNORMALITY OF THE VAS DEFERENS.

By Russell J. Howard, M.S. Lond., F.R.C.S. Eng.,

SURGEON TO OUT-PATIENTS, ROYAL WATERLOO HOSPITAL; ASSISTANT DEMONSTRATOR OF ANATOMY, LONDON HOSPITAL MEDICAL COLLEGE.

RETROVERSION of the testis, a condition in which the epididymis lies anteriorly and the body of the testis with the tunica vaginalis posteriorly, is a not unusual abnormality. It occurs probably in 1 in 20 of all testes and is always to be considered in the diagnosis of testicular disease and in operations upon the genital gland. If this condition be present, the testicle, in a case of vaginal hydrocele, will lie in the front of the fluid and directly under the place usually selected for tapping. Unless the exact position of the testis has been ascertained by the translucent test the trocar may be plunged directly into the gland. In tuberculous epididymitis the hard nodular swelling of epididymitis is found in front of the soft elastic body of the testis and the diagnosis of the disease is obscured unless the condition of retroversion is recognised. In the majority of cases of retroversion of the testis the vas deferens passes down in the tissues of the cord to enter the globus minor of the epididymis in the usual way, and will be the most anterior structure in the scrotum. In the case to be described the testis was retroverted with the epididymis in front, but the vas passed down *behind* the body of the testis and curled round its lower edge. The spermatic cord and the spermatic artery were lying in their usual position in relation to the epididymis and body. About two inches above the globus major the vas left the cord and passed over the *back* of the body of the retroverted testis accompanied only by the artery of the vas and a small plexus of veins. At the lower pole of the testis the vas passed *forwards* to end the globus minor of the epididymis.

patient, which is the main object of the sanatorium, and as a consequence of this the power to treat a larger number of patients. I may be permitted to conclude by expressing my thanks to the staff of the Brompton Hospital for their permission to publish the cases under their care and for their continuous encouragement and useful advice during the whole of my work.

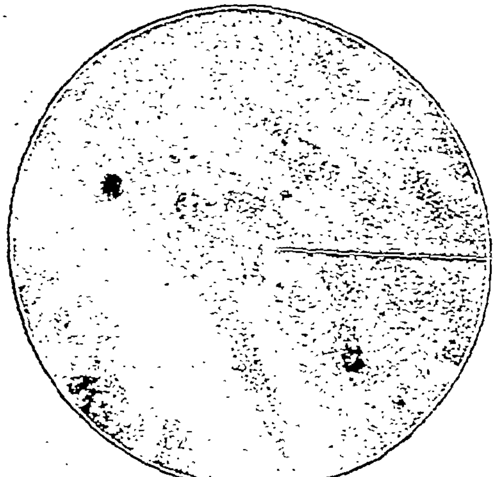
Brompton Consumption Hospital, Fulham-road, S.W.

NOTE ON THE PRESENCE AND SIGNIFICANCE OF CERTAIN ROD-SHAPED BODIES IN THE CELLS OF CARCINOMATOUS TUMOURS.

BY W. FORD ROBERTSON, M.D. EDIN.,
PATHOLOGIST TO THE SCOTTISH ASYLUMS.

IN the course of investigations, of which some of the results have already been described,[1] I had occasion to stain sections of a carcinoma of the breast by the palladium methyl violet method, a staining process that has long been employed for nervous tissues in the laboratory of the Scottish asylums. The preparations obtained, besides serving for the purpose intended, revealed in the protoplasm of very many of the epithelial cells one or more rod-shaped bodies somewhat resembling tubercle bacilli. I have since applied the method to 36 tumours of various kinds and have found that similar rod-shaped bodies are constantly present in certain forms of carcinoma. I have observed them in all of ten carcinomata of the breast, in all of ten squamous epitheliomata, in both of two malignant adenomata of the sigmoid flexure, in a secondary cancer of the liver, in a cancer of the prostate, in a secondary cancerous growth in the dura mater, and in a tumour of the choroid composed of large epithelial cells. I have been unable to detect them in five adenomata of the breast, an adenoma of the cervix uteri, a papilloma, a uterine fibroid, a glioma of the brain, and a spindle-celled sarcoma, as well as in normal squamous epithelium, a mammary gland from a case of puerperal insanity, in a case of chronic mastitis, and in brain tissue.

FIG. 1.

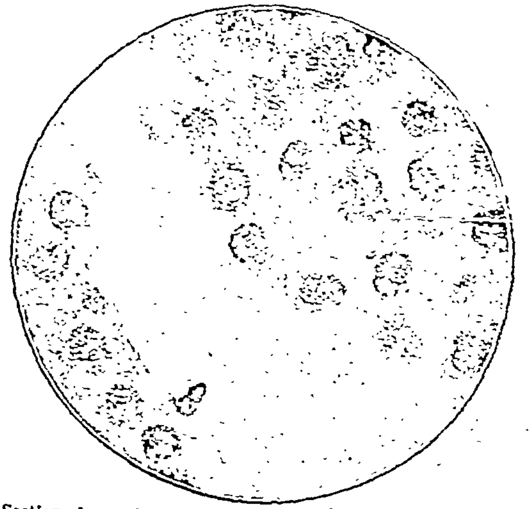


Section of a carcinoma of the breast showing three rods in protoplasm of epithelial cells. Palladium methyl violet method. × 800. The white line indicates the group of rods.

Whilst the most typical form of these bodies is that of a straight or slightly curved rod, closely resembling the tubercle bacillus (about 3μ in length and $0{\cdot}3\mu$ in thickness), much smaller and also much larger forms may frequently be observed in sections in which the bodies in question happen to be numerous. The smaller and medium-sized varieties usually stain evenly of a reddish-violet tint but the larger forms are generally distinctly granular in appearance and may sometimes present one or more pale or colourless transverse bars. The edges are always smooth. The ends are generally blunt and there is no evidence of the presence of flagella. These rods are not stained by Gram's method. In sections stained by the Ziehl-Neelsen method for tubercle bacilli they are invisible. In sections stained with carbol thionin or methylene blue only some of the larger forms can be detected as faintly stained bodies, generally lying in a ground work of the same tint. The rods are most commonly to be seen in the protoplasm of the epithelial cells and they are to be found in largest numbers in the most rapidly growing parts of the tumour (Fig. 1). In the most successful preparations they appear as reddish-violet bodies lying in a pale yellow protoplasm. They are also very commonly, though less frequently, to be observed in the nuclei of the epithelial cells. Regarding their occurrence outside these cells little can be said, because the special staining method also colours the elastic fibres which are generally abundant in these tumours and which, especially if fragmented, cannot be distinguished absolutely from rods similar to those that occur in the protoplasm of the cells. In some special preparations in which elastic fibres have not complicated the picture the rods have appeared to be almost exclusively intracellular.

In five carcinomata of the breast I have found these intracellular rods to be present in very large numbers. In some preparations a hundred or more may readily be counted in a single field under an oil immersion lens. Single epithelial cells may occasionally be observed with from 20 to 30, or even a larger number, lying in their protoplasm (Fig. 2). In five other carcinomata of the breast in which these rods have been detected they appear to be present in comparatively small numbers. I have found them to be numerous in only three squamous epitheliomata; in seven other tumours of this kind in which they have been clearly recognised they occur only occasionally. They have likewise been observed only in small numbers in the other carcinomatous tumours in which they have been detected.

FIG. 2.



Section of a carcinoma of the breast showing numerous rods in the protoplasm of an epithelial cell. Palladium methyl violet method. × 800. The white line indicates the group of rods.

So far as I have been able to ascertain attention has not previously been directed to these peculiar bodies, either by those who have described parasites in carcinomatous tumours or by others. The evidence which can be adduced in support of the view that they are parasitic in nature is, I think, conclusive. They present features which prove them to be growing organisms and they have been cultivated in an artificial medium. The possibility of their being bacilli can be excluded at once. It can be shown that they arise from comparatively large rounded bodies which are certainly not bacterial organisms. It is further to be noted that they have not the characters of the spirochæta microgyrata which has been described as occurring in carcinomata of the mouse.

My observations lead me to conclude that these rod-shaped injection of pilocarpine. Emptying the uterus caused the blood to flow to the portal system and thus lessened the danger of cerebral hæmorrhage. He did not understand the object of the saline injection.—Dr. FAIRBAIRN, in reply, said no attempt had been made to *make an exhaustive collection of cases of apoplexy* as the cause of death in eclampsia, and the cases collected were those of hæmorrhage into the pons or base of the brain without unilateral symptoms to suggest apoplexy. Large cerebral hæmorrhages were not frequent in eclampsia, as was shown by the statistics quoted in the paper. The cases recorded were undoubtedly rare but the possibility of a deeply comatose and cyanosed eclamptic patient having also a cerebral hæmorrhage ought not to be lost sight of, especially in giving a prognosis.

The following specimens were shown :—

Dr. J. P. HEDLEY : (1) Hydrosalpinx with Torsion of the Pedicle ; and (2) Double Hæmorrhagic Cysts of the Ovaries.

Mr. HAROLD S. SINGTON : Tumour of the Fœtal Head.

Dr. A. H. N. LEWERS : Cancer of the Cervix (advanced) ; hysterectomy by Wertheim's method.

MEDICAL SOCIETY OF LONDON.

Graduated Labour in Pulmonary Tuberculosis.—The Opsonic Index in Tuberculous Patients engaged in Physical Exercise.

A MEETING of this society was held on Jan. 13th, Dr. J. KINGSTON FOWLER, the President, being in the chair.

Dr. M. S. PATERSON read a paper on Graduated Labour in Pulmonary Tuberculosis, which is printed at p. 216 of this issue of THE LANCET.

Dr. A. C. INMAN read a paper on the Effect of Exercise on the Opsonic Index of Patients suffering from Pulmonary Tuberculosis ; this also is printed in this issue of THE LANCET (p. 220).

The PRESIDENT said that the two papers which they had just heard marked an epoch in the treatment of pulmonary tuberculosis. He contrasted the work done at the Hospital for Consumption and Diseases of the Chest at Brompton 15 to 20 years ago with the work demonstrated by the two papers read that evening, and pointed out the difference between the groping in the dark then and the light which was now shed on pulmonary tuberculosis.

Sir A. E. WRIGHT, whilst admitting the possibility of the auto-inoculation method being useful, observed that by employing tuberculin they could begin with minimum doses and increase the amount as required, thus insuring more control than in auto-inoculation.

Dr. C. THEODORE WILLIAMS mentioned that when Frimley Sanatorium was opened there was no idea of starting graduated exercises which were begun by Dr. Paterson.

Dr. R. MAGUIRE said that the auto-inoculation treatment must not be applied to every case of pulmonary tuberculosis. Success depended on the careful selection of fit cases for that treatment at the sanatorium ; if the method were to be carried out indiscriminately it would soon be found to fail when compared with artificial inoculation.

Dr. F. J. POYNTON emphasised the importance of recognising that there was more in the sanatorium treatment at Frimley than mere auto inoculation. He did not think that the patients whom they had heard about that evening would have done so well as they did on the tuberculin treatment.

Dr. PATERSON, in reply, dwelt on the necessity of discharging patients from the sanatorium ready to return to their usual work without fear of relapse.

Dr. INMAN, in his reply, said that the advantages of sanatorium life were of inestimable value in the treatment of pulmonary tuberculosis. He did not think that the injection of tuberculin would ever replace artificially induced auto-inoculation.

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases.—Appendicitis.—The Optic Nerve in Cases of Intracranial Tumour.

A MEETING of this society was held on Jan. 15th, Dr. JAMES RITCHIE, the President, being in the chair.

Dr. ROBERT A. FLEMING showed a case of Spastic Diplegia of Infantile Origin in a man aged 45 years. The tendon reflexes were greatly exaggerated, as was also Baginsky's sign. Athetoid movements were present, chiefly in the left arm which was paralysed. Nearly all the muscles were hypertrophied, including those of the neck ; when he spoke there was a marked spasm of the platysma myoides. The patient's intellectual power was good ; there was no family history of nervous disease, but one brother stammered greatly ; the athetoid movements and spasticity had been present as long as the patient could remember. The lesion must have been either a meningo-encephalitis or a meningeal hæmorrhage.

Mr. J. W. DOWDEN showed a man after operation for Perforated Duodenal Ulcer as illustrating the good results of early complete suture of the abdominal wounds. The ulcer was situated towards the gastric end of the duodenum ; it was excised by a longitudinal incision, the cavity of the abdomen was washed out with saline solution, and drainage openings were made at the lower part of the abdomen. On account of the giving way of the sutures the bowels prolapsed two days later ; they were replaced and all the abdominal openings were then securely sutured and healed by first intention.

Mr. F. M. CAIRD showed a man after Removal of Half of the Tongue. The operation was done under cocaine, the tongue being snipped out by scissors. No gag was necessary and the man walked back to bed. A few hours after the operation he could articulate perfectly and the wound healed much more satisfactorily than in cases done under a general anæsthetic. All the glands in the front of the neck were subsequently dissected out, and though each was microscopically examined no trace of malignant disease was found in them.

Dr. EDWIN BRAMWELL showed a boy suffering from Poliencephalomyelitis. He had been healthy until three months ago when he felt sick, vomited, and had pain at the back of the neck. On the following day he could not move his head. The movements of the arms and legs were normal, showing that the spinal cord was unaffected, but his head was held stiffly and this was not due to rigidity of the muscles but to excessive weakness of the deep cervical muscles as well as the sternomastoid and trapezius muscles, which were much wasted and exhibited the reaction of degeneration. A general improvement was taking place and the prognosis was favourable.

Mr. H. ALEXIS THOMSON showed a case after Osteoplastic Amputation *through the Middle of the Leg*, in which a portion of the tibia was retained in the anterior flap and brought into contact with the sawn section.

Dr. D. CHALMERS WATSON showed two cases of Chronic Pancreatitis. He said that the disease was much more common than was supposed. One of the patients had been treated for catarrhal jaundice in August, 1906 ; on account of the pain a neoplasm *at the head of the gall-bladder* was diagnosed and an operation was performed. He was now pale, sallow, and emaciated and subject to severe paroxysmal attacks of ague-like severity every six weeks. The second patient had suffered for ten years with indigestion, jaundice, and emaciation.

Mr. DOWDEN read a communication entitled "Deductions from 100 Consecutive Operations for Appendicitis." He confined his statements almost entirely to acute attacks. He said that the appendix was dependent on a single artery as a rule for its blood-supply and was consequently unable to cope satisfactorily with the urgent demands for blood caused by severe inflammation. In his series of 100 operations 82 were acute cases (52 males and 30 females), while the so-called "interval operation" was performed on 14 males and four females. Recurrent attacks were noted in 37 cases. Among the 82 acute cases there were 16 deaths, while among the 18 "interval cases" there were no deaths. A classification of the acute cases according to age showed that 16 cases with six deaths were under 16 years of age ; 50 cases with 9 deaths were from 16 to 30 years of age ; and 16 cases, with one death, were over 30 years. On the first day of the illness there were 11 operations performed with no death ; on the second day there were 16 operations with two deaths ; on the third day there were 18 operations with seven deaths ; and at later periods there were 37 operations with seven deaths. The symptoms were often treated as those of acute indigestion. It could not be *sufficiently emphasised* that every attack of so-called acute or subacute indigestion called for a careful local examination, including, if in doubt, a rectal examination. The presence of pain to the left of, and

20 minutes to half an hour to the action of liquid air. They were then at once introduced into healthy mice beneath the skin, the presumption being that in these circumstances the tumour cells would be destroyed by the action of the liquid air, and consequently that they would multiply no further. However, among the inoculations made with the frozen material it was found that in some cases new tumours were produced. Further, in a number of mice wherein tumours of the same strain were already growing similar inoculations were made in a remote part of the body; in some of these also the same positive result was obtained. From these observations it is rendered *clear that exposure to* liquid air at a temperature of about – 195° does not necessarily destroy the potentiality of the substance of a mouse tumour to produce fresh tumours of the same kind in mice into which such frozen tumour substance has been grafted.

These facts in themselves are somewhat surprising, and they immediately raise a number of questions which it will be desirable to have elucidated in the interests of research concerning the nature of cancer. *In the first place, it is* rendered clear that exposure to liquid air for a certain period of time does not destroy the principle upon which the vitality of mouse cancer depends. If, as may be the case, the cells composing the mass of the tumour, and constituting the grafts, are killed by exposure to liquid air, then the development of mouse cancer after such exposure indicates not merely that the growth of similar tumours is independent of the integrity of the "cancer cells," but also that the new tissues are not necessarily formed from the implanted cells at all, and may arise from the cells of the new host in response to some stimulus introduced along with the frozen material, and quite independent of the integrity of the so-called "cancer cells."

This matter is at present engaging our attention, but the *fact* that the capacity for originating new growths is not necessarily destroyed in the substance of tumours after exposure to liquid air, certainly suggests that the production of new tumours in the hosts into which the frozen cancer tissue has been introduced may possibly not be dependent upon the introduction of *the "cancer cells"* at all, but upon the action of a virus which is independent of these cells, and retains its activity after being subjected to the temperature of liquid air. It is well known that a number of bacteria are not killed by this temperature. The fact that cancer can be originated in mice by implantation of portions of frozen tumours may indicate that there exists some such cause as an organised irritant or parasite acting as an agent in the production of cancer. *On* the other hand, however, it is not yet certain that the cells from the tumour introduced into a new individual are killed by half an hour's exposure to the temperature of liquid air, particularly as the seeds of some plants and *trypanosomes* are said to survive this temperature.

NOTE UPON THE EFFECT OF LIQUID AIR UPON THE GRAFTABLE CANCER OF MICE.

BY J. E. SALVIN-MOORE, A.R.C.S., F.L.S., F.Z.S.,
PROFESSOR OF EXPERIMENTAL AND PATHOLOGICAL CYTOLOGY AND DIRECTOR OF THE CANCER RESEARCH LABORATORIES, UNIVERSITY OF LIVERPOOL;

AND

J. O. WAKELIN BARRATT, D.Sc., M.D. LOND., F.R.C.S. ENG.

IN the present communication we wish to record some observations made upon the graftable tumours of mice. The tumours under observation were obtained for the Liverpool Cancer Research Laboratories, through the kindness of Professor Bang of Copenhagen, and were received originally from Professor Jensen. For purposes of certain experiments not yet completed fragments of the tumour in question were placed in liquid air for from 20 minutes to half an hour and after thawing were placed under the skin of fresh mice in the ordinary way. It was presumed that by exposure to the temperature of liquid air the tumour cells would be immediately killed. However, in a number of such grafts after a period of from ten to 20 days fresh tumours appeared at the site of the inoculations.

These observations appear to be of interest in themselves; but more especially so because they lead up to a number of important questions. It seems to be probable from what *has been observed in relation to* healthy skin that exposure to the temperature in liquid air rapidly kills the cells composing it. It may, of course, be that cancer cells differ in their capacity to resist such a temperature, but at the same time since some bacteria and other organisms are known not to be killed by the temperature in question it is clearly suggested that there may be an organism in or among the cancer cells able to withstand the treatment to which they have been *subjected and afterwards consequently capable of setting up* the formation of a tumour derived from the tissues of a new host. These are, however, matters which are engaging our attention and at present it is undesirable to say more concerning them.

TREATMENT OF GRAVES'S DISEASE WITH THE MILK OF THYROIDLESS GOATS.

BY WALTER EDMUNDS, M.A., M.C. CANTAB.; F.R.C.S. ENG.;
SURGEON TO THE PRINCE OF WALES'S HOSPITAL, TOTTENHAM.

SINCE the discovery of the nature of myxœdema it has been thought that the symptoms of Graves's disease are due to an excessive secretion from the enlarged thyroid gland. Further, it has been thought that a remedy might be found in the serum or milk of thyroidless animals, the idea being that to counteract the thyroid secretion the normal body secretes an antithyroidin, and that in thyroidless animals this antithyroidin would be in excess and available to act as an antidote to the excess of thyroid secretion in Graves's disease.

There are, however, some difficulties in the way of this theory. The severity of the symptoms of Graves's disease is by no means always in proportion to the size of the goitre, nor is this always one of the first symptoms; indeed, from the history of the cases it would seem that they often start from some mental strain. Another difficulty arises from the fact that myxœdema and Graves's disease sometimes coexist. Babinski mentions two such cases and Dr. Samuel West has recently recorded a very clear case occurring under his care at St. Bartholomew's Hospital.

A third difficulty arises from the symptoms produced by the excision of the thyroid varying in different animals. In dogs and cats the operation produces severe nervous symptoms, tremors, paralysis, and convulsions, quickly followed by death. In goats, on the other hand, as a rule no ill effects follow. I have recently performed the operation on ten goats. One of them was young and not fully grown; the effect of the operation was that it ceased to grow and became in fact a cretin. The other nine goats were fully grown and in seven of them the operation produced no effect; in the other two there came on after some months a swelling of the face, due no doubt to myxœdema; this was treated with thyroid tabloids and disappeared but both animals died. A small percentage of the dogs submitted to complete thyroidectomy escape the acute symptoms; they then remain well; they do not later develop myxœdema nor does this occur in those dogs in which nearly the whole of the thyroid gland is removed and one or more parathyroids are left. Thus dogs do not have myxœdema and goats do not have the acute nervous symptoms which occur in dogs and which are attributed by Gley and others to the removal of the parathyroid glands. Monkeys, however, which are nearer to man than either dogs or goats, may have aparathyroidea or myxœdema or both. As a rule, it seems that monkeys when submitted to thyroidectomy die from the nerve symptoms; those, however, which survive or escape this may have, and some do have, myxœdema.

Thus, even if it is admitted that the symptoms of Graves's disease are due to the thyroid secretion, the question may not be merely one of too much or too little, but we may have to distinguish between the secretion from the thyroid proper and that from the parathyroids.

A fourth, and last, objection to the theory is that it leaves out of account the possibility of any action of the central nervous system on the secretion of the gland. Exner, and later myself, have shown reason for thinking that there is and it grew high up and into the innominate vein. It projected into the right auricle of the heart and filled it up, and projected into the ventricle.

Dr. HENRY C. EARL exhibited a specimen of Extensive Lympho-sarcoma in the Upper Parts of the Thorax but lying more in front of the structures than surrounding them. It grew down on to the pericardium and the heart was covered all over with a thick layer of tumour. It extended to the left pleura and from it into the lung. There were also several globular secondary growths in the liver of the same structure.

Dr. WILLIAM BOXWELL exhibited a specimen of Aortic Aneurysm taken from a man, aged 33 years. At the necropsy the aorta was found to be the seat of a saccular aneurysm of the size of a duck's egg. The innominate artery was involved in the aneurysm, while the left carotid and subclavian opened directly into the sac. The aneurysm lay directly under the right sterno-clavicular articulation and caused a partial dislocation of the joint. The sac was crossed in front by the left innominate vein, which was incorporated in its wall and nearly obliterated, its function having been taken on by an enlarged left superior intercostal. Both recurrent nerves must have been subjected to considerable pressure, as were also the trachea and œsophagus.

Dr. BOXWELL also showed specimens obtained from two cases of Poisoning by Crude Phenol. The first patient was a girl, aged 15 years, who swallowed four ounces of the poison. She was dead when brought to hospital and the necropsy was made about 24 hours afterwards, no attempt having been made to counteract the effects. The stomach was of a leathery consistence; the serous surface was dull and of a bright cherry-red colour. The same appearances were noticeable on the contiguous surface of the spleen. The mucosa of the stomach and œsophagus was hard and brittle, dull greyish-white in colour, with whiter points resembling incrustations, as if roughly painted with white lead. There was no evidence of this necrosis on the tongue or fauces, although in the latter an œdematous condition of the mucous membrane was very remarkable. The second patient was a child, aged 12 months. The amount of the poison swallowed could not be accurately ascertained. The child was still alive when removed to the hospital. About four ounces of whisky were administered within a few minutes of the dose of phenol, followed by a copious irrigation of whisky and water. There was no other antidote used. The amount of coagulation necrosis was not great, the stomach bearing a marked contrast to that of the previous case. The condition of the pharynx and œsophagus in the two cases was much the same. Some details of a third case were also given, where a woman, aged 27 years, had swallowed eight ounces of crude phenol. She also was treated with whisky, whisky and water, and glycerine and water given through a stomach-tube. A considerable quantity of brown fluid smelling strongly of carbolic acid was syphoned off with the initial dose of whisky and as a result of the treatment the woman was doing well. It was a remarkable fact that within a few minutes of the administration of whisky she recovered consciousness and within an hour was vomiting naturally.

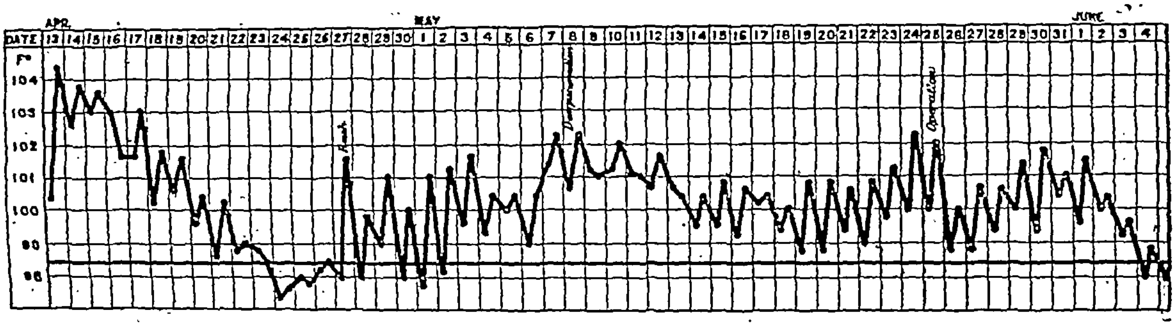
The SECRETARY exhibited an old museum specimen showing a Round Worm doubled up in the trachea and larynx of a child.

SOUTH-WEST LONDON MEDICAL SOCIETY.—A meeting of this society was held on Jan. 8th, Dr. A. Dumville Roe, the President, being in the chair.—Mr. Charles Ryall opened a discussion on the Diagnosis and Treatment of Hæmorrhage from the Mouth, Nose, and Stomach. Dealing chiefly with hæmorrhage from the stomach Mr. Ryall spoke of the importance of accurate diagnosis and of keeping in mind the possibility of carcinoma supervening on what appears to be a simple chronic inflammatory condition. He referred in detail to the condition known as gastrostaxis and to the hæmorrhage in cirrhosis of the liver and from the œsophagus. Treatment of severe hæmorrhage resolved itself into the use of morphine and rest. Drugs were of little use except in less severe cases; ice, which should be ground, was useful, and the ice-bag when used should not be allowed to produce pressure on the abdomen. Gastro-enterostomy was frequently successful in removing the more prominent troubles in suitable cases. Mr. Ryall having briefly referred to bleeding from the nose and mouth, the discussion was continued by the President.—Mr. Mark Robinson inquired what was the reason that the presence of blood in the stomach induced vomiting.—Mr. J. Gay spoke of hæmatemesis in hysteria, and referring to epistaxis wondered if plugging the posterior nares was not less frequently required nowadays. He had found that in a large number of cases the hæmorrhage came from a septal vessel just within the nares where it could be easily controlled.—Mr. E. F. White thought that drugs were useless in severe cases. He had administered adrenal with little local effect and had seen toxic symptoms arise from over-absorption. He had had experience of hæmorrhage from the dilated veins of the œsophagus and noted that in duodenal ulcer the course was commonly more rapidly downhill than in any form of gastric ulcer.—Dr. M. G. Biggs agreed that a large number of cases of epistaxis were due to the rupture of a septal artery. He had had experience of gastrostaxis which was more alarming to the medical attendant than to the patient who was used to it. He inquired whether the view of the Leeds school that all gastric ulcers should be excised when discovered as a precaution against subsequent carcinoma was widely held and practised.—Mr. Aitken recorded two cases of gastrostaxis and advocated an absolute starvation in all cases of gastric ulcer. He had found calcium chloride of little use unless it was given in teaspoonful doses of the dry salt; in that form much benefit appeared to be obtained.—Dr. W. G. Dickinson mentioned two cases of sudden death from gastric hæmorrhage, and Dr. R. Carswell, Dr. C. E. McDade, and Mr. E. J. Pritchard joined in the discussion which was closed by Mr. Ryall.

ÆSCULAPIAN SOCIETY.—A meeting of this society was held on Jan. 17th, when Dr. W. Langdon Brown, the President, showed the following cases:—1. A man, aged 29 years, with Congenital Heart Disease, who had well-marked clubbed fingers, hæmoptysis, and a systolic apical murmur. The condition was probably one of patent septum ventriculorum. 2. Two children, brother and sister, with Congenital Defects The boy, aged three years, had congenital heart disease. He had marked cyanosis, clubbed fingers, and a systolic apical murmur due to an imperfect septum. The girl, aged nine months, had her left hand like a flapper, absence of nearly the whole of the radius and of the thumb. 3. A man, aged 59 years, with Melanotic Sarcoma of the Lung. Four years ago he had his right eye removed for "cancer." Six months ago he had five and a half pints of blood-stained fluid removed from a left-sided pleural effusion. There was bulging of the left side of the chest posteriorly in the lower half. There were markedly enlarged veins over the upper chest and the lower abdomen on the left side, the blood flowing away from the bulging area. There were several small nodules over the abdomen and the chest, and a shotty nodule above the left clavicle was excised and found to be melanotic sarcoma.—The President also showed the Heart of a man, aged 39 years, who had died from well-marked Stokes-Adams Syndrome.—Dr. L. U. Young showed a Fibroma of the size of a large orange which he had removed from the left labium majus of a healthy, muscular woman, aged 21 years, and which had existed for from four to five years.—Dr. D. Ross demonstrated a well-nourished lad, aged 18 years, who was a typical Ruminant. From 15 to 20 minutes after a meal, at intervals of about four minutes, the food returned by mouthfuls, to be remasticated and again swallowed. It occurred mostly when he ate hurriedly and was unattended by nausea, retching, or discomfort. Farinaceous foods and those containing cellulose almost invariably regurgitated. He described the second mastication as giving rise to a pleasant sensation. The condition was probably a motor gastric reflex neurosis.—Dr. Ross also showed a man, aged 47 years, who had undergone Gastro-enterostomy for Cancer of the Wall of the Stomach and who had very much improved since the operation.

EDINBURGH ROYAL MEDICAL SOCIETY.—At a meeting of this society held on Jan. 10th Professor Robert Muir (Glasgow) gave a demonstration on Repair, Hypertrophy, and Tumour Growth in the Liver. His results were taken from human livers which had come into his hands and hence were of more value than experimental results. In a case of 14 days' old rupture of the liver there was clearly seen evidence of proliferation of the epithelium of the bile ducts to form new liver cells and also of hypertrophy and proliferation of the uninjured liver cells to increase their functional power. Cells undergoing this proliferative change were found larger, less granular, and often multinucleated. The result of such changes was irregularity in shape and size.

general condition of the patient did not improve. There was great prostration and frequent vomiting, the vomit consisting first of thin yellow and later of dark green material. The tongue and mouth were in a very foul condition. This state lasted for six days. On the 27th the temperature again rose to 101·6° F. and the pulse to 136 per minute. A generalised erythematous rash, accompanied by severe sore-throat, appeared and persisted for three and a half days. A diagnosis of scarlet fever was made and the patient was isolated. He had some diarrhœa but there was nothing noteworthy in the stools. From the 27th to May 3rd the temperature was intermittent. Nothing abnormal was detected in the chest and a gradual improvement in the general condition followed, the vomiting ceasing and the tongue becoming clear. The urine had constantly contained albumin. On the 8th desquamation began and during the next fortnight the temperature remained considerably elevated (see chart).



About May 20th or 21st the patient first complained of pain in the neck and a tender swelling was discovered in the region of the right lobe of the thyroid. The patient then told us that he had known of the existence of a swelling in this situation for some years but that it had not caused any symptoms. By the 24th the tumour had rapidly increased in size and was exceedingly tender. It moved up and down on swallowing but did not cause any dyspnœa or dysphagia. The swelling occupied the greater part of the right lobe of the thyroid; it was globular in shape, very elastic, but not definitely fluctuating. The left lobe was normal and the trachea was displaced to the left side of the mid-line. The temperature, which had continued to be intermittent, rose on the evening of the 24th to 102·2°. A diagnosis of suppuration in a thyroid adenoma was made.

On May 25th a transverse incision was made over the lower part of the swelling. The infrahyoid muscles were found to be œdematous and adherent to the swelling; they were divided and then peeled off its surface. An attempt was made to enucleate the tumour, but in doing so it was ruptured and two ounces of pus were evacuated. A couple of drainage-tubes were placed in the cavity, one of them being brought out at the posterior border of the sterno-mastoid through a separate incision and the other one through the middle of the incision, which was only partially closed by two or three stitches, the rest being packed with gauze. The tubes were left out on the 29th. By June 17th the incision had quite healed, and all pain, swelling, and tenderness had disappeared. For a week after the operation, in spite of the local condition being quite satisfactory and of there being no evidence of insufficient drainage, the temperature remained constantly above normal. The pulse-rate was about 100, and the respirations were 24 per minute. On June 4th the temperature came down to normal permanently and convalescence was thereafter uninterrupted.

Films made from the pus at the time of the operation showed that the cells were nearly all polynuclears, and very few organisms were seen. Cultures, however, gave a copious and pure growth of a non-Gram-staining motile bacillus, which on further chemical examination gave the fermentation and other reactions of the typhoid bacillus in a typical manner. The bacilli were readily clumped by a human and animal typhoid serum in high dilutions. The patient's own serum with a 1 in 50 dilution gave a positive Widal's reaction on two separate occasions at a week's interval. There can be no doubt that this was a case of suppuration in a thyroid adenoma due to the typhoid bacillus.

The interesting point is, from what source did the organisms reach the gland? As already described, the illness was by no means of the ordinary typhoid type, and after the bacilli had been found we carefully examined the abdomen for enlargement of the spleen but failed to detect it or any other abnormal condition suggesting typhoid fever. The stools did not at any time have the characters of those of a typhoid patient. Moreover, the patient made such a rapid recovery that he was able to leave the hospital on June 22nd. We questioned him as to his having had typhoid fever in the past, but we were unable to satisfy ourselves on this point.

We have thought this case to be worth publishing because an acute abscess in the thyroid, though a well-recognised condition, is not of very common occurrence, and when it does occur, apart from traumatism, such as puncturing a cyst, is most often observed in connexion with an acute febrile disease and generally at a late stage of the illness. Typhoid fever is one of the commoner of such diseases to be followed by an acute thyroiditis and usually the abscess is a late complication. In this patient the signs developed at the end of the sixth week from the beginning of the illness. As soon as suppuration has occurred the pus should be evacuated, or if the abscess has developed in an encapsuled tumour enucleation should, if possible, be performed. If left, the pus is very likely to penetrate the gland capsule, leading to diffuse cellulitis of the neck and mediastinum or to burst into the trachea or pharynx. Whichever of these events occurs the result is likely to be very disastrous. And free drainage must be provided at the time the pus is let out. The incision should not be closely sutured; if a transverse incision is made the scar is very little noticeable. In this patient it is a thin curved line.

We are indebted to Dr. W. d'Este Emery for kindly undertaking the pathological investigation.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

◆

NOTE ON A CASE OF FENESTRATION OF THE ANTERIOR PILLARS OF THE FAUCES.

BY P. WATSON WILLIAMS, M.D. LOND.,
LECTURER ON DISEASES OF THE NOSE AND THROAT, UNIVERSITY COLLEGE, BRISTOL; LARYNGOLOGIST AND RHINOLOGIST, BRISTOL ROYAL INFIRMARY; AND CONSULTING SURGEON FOR DISEASES OF THE EAR, NOSE, AND THROAT, PONTYPOOL HOSPITAL.

THE exact mode of origin of this peculiar condition is a disputed point. Some of the cases recorded were considered to be congenital, in others it is believed to be caused by ulceration due to scarlet fever. I consider that this case looks like a congenital defect on account of (1) the absence of any cicatrices or unevenness in the margins of the fenestræ; (2) the bilateral symmetry of the malformation; (3) the arrangement of the strands of mucous membrane and the muscle fibres, and that they obviously correspond to the anterior pillars of the fauces, as shown in the drawing; and (4) the fact that although the posterior faucial pillars do not show fenestration yet the palato-pharyngeus muscles are collected into a separate bundle of fibres on each side, with only a thin layer of mucous membrane in continuity with the lateral walls of the pharynx. Thus, in front the palato-glossus muscle forms a separate bundle, passing down to the tongue, and forms the inner boundary of a contained useful knowledge and even new facts. Too often the teaching was gilt, not golden. Since medicine has become more a science and less an art this sort of literature has begun to die out. We watch its death struggles with equanimity, though when some peculiarly aggressive flicker of vitality manifests itself we are inclined to wish that it would "get on with its dying." We may regret the deterioration of literary style and deplore the too frequent lapses of grammar and composition which characterise so many of the medical writings of to-day, but we may be proud of the fact that while these defects are only too patent the science of medicine forges ahead by leaps and bounds.

The volume before us combines some of the virtues of both the old and the new types. It is well printed on large pages, with wide margins, uncut edges, and a gilt top; it is sumptuously illustrated—quite an *édition de luxe*. It is true that most of the subject matter will be found in any good treatise on diseases of the eye but it is brought forward here in such a pleasant fashion that it may well prove attractive to the busy general practitioner, for whom, we presume, it is primarily intended. There are many things in it which will be of interest and value to the trained ophthalmologist, for he cannot but benefit by the ripe experience of a distinguished *confrère*. His attitude must necessarily be a critical one. He will regret the incompleteness of the book as a treatise on injuries of the eye. We cannot think that he will always agree with the author's methods and still less with his views on some points of ocular pathology. As examples of the first-named he may doubt the advisability of attempting to replace a prolapsed iris after an ordinary injury and of aiding this procedure by the instillation of eserine. Separating the conjunctiva all round the cornea, passing a purse-string suture through its free margin, and pulling this tight so as completely to cover the cornea, will only exceptionally be indicated, in his estimation, in the treatment of perforating wounds. He will probably prefer to introduce a glass ball rather than paraffin into Tenon's capsule as a modification of enucleation. The author's views on the theory of sympathetic ophthalmia savour of antiquity. "Numerous experiments have conclusively demonstrated that irritation of the ciliary nerves in one eye produces not only dilatation of the blood-vessels but also increased secretion of albumin into the aqueous humour of the other." Römer's recent extremely delicate experiments entirely, and in our opinion conclusively, negative this statement.

Dr. Ramsay describes the methods of determining the presence, and localising the situation, of intraocular foreign bodies. The large magnet which he uses is apparently the same as Volkmann's; he considers it preferable to Haab's. The chapter on ocular therapeutics is the one which will most attract the ophthalmologist, for it gives many hints of the author's predilections in drugs. He rightly lays stress on the general treatment of the patient, which is too often forgotten in the absorbing interest of the local condition. Various silver preparations, anæsthetics, mydriatrics, and so on, are passed in review and attention is drawn to the indications for subconjunctival injections. The formulæ in use at the Glasgow Ophthalmic Institution form an appendix to the work.

Special note must be taken of the coloured plates which adorn the book. The drawings of the eyes are extremely good but the artist has been unfortunate in his choice of a skin tint. The foreigner glancing through the book might conclude that Dr. Ramsay has an extensive practice amongst negroes. The outline drawings contain many inaccuracies. Two plates illustrate Dr. Thomas Reid's unorthodox histological views; it would have been well to point out that these views are not generally accepted by histologists.

In conclusion, we may express a doubt as to whether books of this kind are worth the trouble and expense which they entail. Do beautifully reproduced coloured drawings of common pathological external conditions serve any very useful purpose? We think not. Anyone will learn far more from careful examination of the patients and no one will be made much more competent to treat such cases by study of the drawings.

Plasma und Zelle. Erste Abteilung: Allgemeine Anatomie der lebendigen Masse. Bearbeitet von Professor Dr. MARTIN HEIDENHAIN in Tübingen. Erste Lieferung: Die Grundlagen der mikroskopischen Anatomie, die Kerne, die Centren und die Granulalehre. (*Plasma and Cell.* First Section: General Anatomy of Living Matter. Edited by Professor MARTIN HEIDENHAIN of Tübingen. First Part: The Elements of Microscopical Anatomy, the Nuclei, the Centrosomes, and the Granule Theory.) With 276 (in part coloured) illustrations in the text. Jena: Gustav Fischer. 1907. Pp. 506. Price M.20; to subscribers M.16.

THIS work of Professor Heidenhain, which constitutes the last part of Bardeleben's "Handbuch der Anatomie des Menschen," has appeared at a most opportune moment and supplies a work the need of which has been very greatly felt. The author, as it were, here "puts the finishing touches" to our knowledge as regards many points of vital interest in the study of this subject. The anatomical aspect of living matter is the chief point under consideration, but the author also, in a most comprehensive and interesting manner, touches upon the various branches of biology. No such complete treatise on this subject has hitherto been published and we strongly recommend the book to every medical man who is interested in the biological side of his profession. It cannot fail also to be of great benefit to biologists as a book of reference and we are confident that it will be received by them with all the enthusiasm which it deserves.

Professor Heidenhain, as usual, proves himself complete master of his subject. The general aspect which he puts forth in dealing with the different problems is a very pleasing one and comprises the biology of the cell in the full sense of the word. He gives a fairly comprehensive review of the historical development of our anatomical and biological knowledge of the cell in general. Here and there we find the author's own ideas put forth. In the question of the differentiation of living matter he considers that there is no constant connexion between the structure of the nucleus and the function of the protoplasm. Regarded from a general point of view, the nuclei of the tissue cells are markedly inactive. The work also contains much interesting and instructive information as regards the chemistry both of the nucleus and of the protoplasm. The methods of staining, and so on, are also considered but the author does not go into detail concerning this subject.

In several minor points we are able to agree with the ideas set forth by the author. For instance, we consider that the lining of the cell plays quite as important a rôle as the author seems to indicate. It is a noteworthy fact that, although he does not actually commit himself to any decided opinion, he yet does not appear to support the hypothesis of the individuality of the chromosomes. The important subject of spermatogenesis is a point upon which the author has enlarged and with which he has dealt in a comprehensive, interesting, and altogether satisfactory manner. In the fourth portion of the first part Professor Heidenhain deals fully with our knowledge of the granules. Altmann's theory that the granules are active parts of the protoplasm, granulation in gland cells, mitochondria, the vital staining of the granules, and so on, are points which are noted. In the last chapter the protomere theory—i.e., the composition of the plasma out of minute dividing particles—is gone into at some length.

In conclusion, we should like to draw attention to the complete bibliography which is given at the end of each chapter. The value and interest of the work are also much enhanced

The case was of interest on account of the unusual physical signs presented. The patient was 51 years of age, and had suffered from caries of the spine when he was 32 years old. Twelve weeks before he was admitted into the London Hospital (under the care of Mr. F. S. Eve) the left testis had become swollen and painful. Nine weeks after the swelling first appeared a soft red spot was discovered in the *front* of the scrotum which enlarged and eventually burst, discharging pus. On examination in hospital there was an abscess with a sinus in the anterior wall of the scrotum. Behind the abscess a hard nodular mass was felt which later was found to be the tuberculous epididymis and behind that a soft globular structure which was the body of the testis. The vas could be felt in the spermatic cord; it was not beaded. On examination by the rectum the left vesicula was found to be swollen and hard.

Orchidectomy was performed 12 weeks after the first symptoms and as much of the vas as possible was removed. The epididymis was quite destroyed by tuberculous deposits and many nodules of tubercle were scattered through the body of the testis. The abscess cavity opened into the globus major of the epididymis. The wound healed by the first intention.

I am indebted to Mr. Eve for kindly allowing me to publish the case.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION.

Enucleation of a Uterine Fibro-myoma during the Seventh Month of Pregnancy.—Hæmorrhage into the Pons Varolii as the Immediate Cause of Death in the Eclampsia of Pregnancy.—Exhibition of Specimens.

A MEETING of this section was held on Jan. 9th, Dr. HERBERT R. SPENCER, the President, being in the chair.

Dr. HERBERT WILLIAMSON read a short communication on a case of Enucleation, during the seventh month of pregnancy, of a Uterine Fibro-myoma weighing 17½ pounds, which was followed by premature labour two days later. The patient was a primigravida, aged 32 years. When four months pregnant she suffered from repeated attacks of acute abdominal pain and became emaciated with some fever, and the distension of the abdomen was so great that she was unable to lie down in bed. At the time of the operation the tumour, which could be felt distinct from the gravid uterus, was thought to be a malignant growth of the ovary, but it was found to be a uterine fibro-myoma undergoing necrotic degeneration. The area of attachment of the tumour to the uterus was rather narrow but required enucleation. A premature child was expelled three days later but the patient made an uninterrupted recovery.

Dr. NORMAN C. CARVER and Dr. JOHN S. FAIRBAIRN communicated a case of Hæmorrhage into the Pons Varolii as the Immediate Cause of Death in the Eclampsia of Pregnancy, with illustrative cases. The patient was a primigravida, aged 24 years, who, after exhibiting signs of impending eclampsia, was found unconscious and straightway admitted to hospital. In view of the history of the illness and the presence of œdema and a high degree of albuminuria the case was thought to be one of eclampsia, and as the patient was in a state of deep coma, with Cheyne-Stokes respiration, rapid dilatation of the cervix was done, followed by the extraction of a fœtus of between five and six months' development. The patient died a few hours later and at the necropsy death was found to be due to an extensive hæmorrhage into the pons Varolii. Dr. Carver and Dr. Fairbairn argued that although the immediate cause of death was a pontine hæmorrhage the case was primarily one of eclampsia, and in support of this quoted four recorded cases of a similar nature, in which an unsuspected cerebral hæmorrhage was found post mortem. Details of these cases were given and, from an analysis of the symptoms presented by them and the above case, attention was drawn to such features in them as might serve to arouse a suspicion of the occurrence of apoplexy in the course of an eclamptic attack. These were, briefly, deep coma and cyanosis, with marked respiratory disturbance, occurring in a young patient presenting the urinary and other signs of eclampsia, and they were especially suggestive when the attack was unaccompanied by the usual eclamptic convulsions.—The PRESIDENT thanked Dr. Carver and Dr. Fairbairn for the interesting paper. He had not met with a case of hæmorrhage into the pons Varolii in eclampsia but he could recall two cases of hæmorrhage into the substance of the brain, one observed at a post-mortem examination and the other in which hemiplegia occurred, from which the patient slowly recovered. He thought that apoplexy was a well-known cause of death in eclampsia, and was surprised that Dr. Carver and Dr. Fairbairn had not found more cases recorded, although they did not claim that their paper was exhaustive. In view of the possibility of the occurrence of cerebral hæmorrhage in eclampsia, the intravenous injection of a large quantity of saline fluid would appear to be not unattended with risk.—Dr. MACNAUGHTON-JONES recalled the fact that the "apoplectiform" was one of the old writers' divisions of eclampsia in which sanguineous and serous effusion occurred into the ventricles. The symptoms were such as described in this case. He dwelt on the importance of early anticipation of the eclampsia, especially through the ocular symptoms and signs which were often present, and in which an ophthalmoscopic examination afforded most valuable evidence of the approaching danger. One of the most valuable therapeutical means they possessed to control the increased blood pressure in these cases of threatening cerebral hæmorrhage he believed to be the employment of weak doses of pilocarpine which was also useful in checking the convulsions. If necessary, its full physiological action might be neutralised by $\frac{1}{150}$th of a grain of atropine. He had known eclampsia ending fatally to occur as early as the fourth month of pregnancy.—Mr. A. LIONEL HALL SMITH said he had seen three cases of cerebral hæmorrhage complicating eclampsia or toxæmia of pregnancy, in all of which the diagnosis was confirmed at the necropsy. In one of them the hæmorrhage occurred in association with eclamptic convulsions after delivery, but in the other two the patients were not in labour and had only reached about the thirtieth week of pregnancy.—Dr. AMAND J. M. ROUTH had not had an opportunity of seeing a post-mortem examination of any case dying from puerperal eclampsia where cerebral hæmorrhage had been found, but thought that Dr. Carver and Dr. Fairbairn had shown how often such hæmorrhage might supervene and be the immediate cause of death. He thought it unwise to increase arterial tension, as must have been done in the first case reported, when 10 ounces of blood were removed and 40 ounces of saline infusion injected. This may well have increased the tendency to hæmorrhage. He presumed that saline infusion in these cases was given to dilute the toxins at each given point and to increase the leucocytosis to combat the toxins; but it was doubtful if it should be given when it increased arterial pressure. He considered that the suggestion to give pilocarpine (at all events in the doses usually prescribed—viz., $\frac{1}{4}$th grain) was fraught with grave danger. He considered that it should never be given in cases where apoplectic symptoms were present or where there was coma, for he had seen patients under its influence suffocated by the enormous quantity of ropy mucus secreted by their salivary and broncho-pharyngeal glands. He was interested in the fact that epigastric pain had been mentioned as a precursor of eclampsia in some of these cases of albuminuria of pregnancy. He considered this sign, following ocular evidences of high arterial tension, increasing albuminuria, and diminishing excretion of urea, a valuable indication that eclampsia was impending and that steps should be taken to induce labour without needless delay.—Mr. D. C. RAYNER referred to a case of eclampsia under his care in which a fatal termination was due to cerebral hæmorrhage. The patient was in the eighth month of her third pregnancy when convulsions set in. They were frequent and seemed more marked on the right side. The pupils were also noticed to be unequal. The urine contained albumin and the patient was not in labour. Coma deepened and the patient died in a few hours. There was extensive hæmorrhage into the right corpus striatum and optic thalamus.—Dr. R. H. HODGSON said that he thought the lesson to be learnt from this instructive paper was, in al cases of eclampsia in pregnant women empty the uterus He had done so in six cases and in all the women recovered, five very rapidly, and one in whom some sligh convulsions continued for five days was quite well after one salts and their metabolism in the body has been extended and is a useful study of the subject. The consideration of beverages is also full and includes tables of the composition of the most important mineral waters and a useful summary of the effects of alcohol and of its uses in health and disease, in which the opinions of several authorities are quoted at some length. The effects of a number of factors upon foods and their use in diets are given, including the questions of the concentration, the preservation, and the cooking of foods, and of food adulteration and the varieties of food poisoning. The subject of the feeding of infants is very fully dealt with and this section is one of the best in the book. The diets adapted to special conditions are given, such as those for the aged and those advised during pregnancy. In this connexion the dietary recommended by Prochownick in pregnancy with pelvic contraction is given in detail. About half the book is devoted to the presentation of diet in disease; each disease is separately considered and various diets are suggested in many cases. This method is a convenient one, since, although it involves considerable repetition, it facilitates the use of the book as a work of reference. In most cases not only is the total quantity of food to be given indicated but also the times at which the meals are best taken and also the amount of fluid to be permitted. Where different diets are advised by several authorities these are clearly separated from one another and are discussed by the authors. Various forms of dietary used in institutions are given in detail with their heat values. A chapter is devoted to recipes for beverages and special articles of diet. The concluding section consists of lists of substances which may and may not be given in various diseases, constituting what the authors term "rapid reference diet lists."

The book is well printed, is easy of reference, and is a valuable presentation of the subject of which it treats.

LIBRARY TABLE.

An Introduction to Physiology. By WILLIAM TOWNSEND PORTER, M.D., Associate Professor of Physiology in the Harvard Medical School. London and Philadelphia: J. B. Lippincott Company. 1906. Pp. 587.—This work is drawn up to meet the requirements of the "concentration" system as practised in Harvard Medical School at Boston, a system which means that the student at the time shall study only one principal subject such as pathology or physiology. In Harvard the first half year in the medical school is devoted to anatomy and histology, and the second to physiology and biological chemistry. The traditional teaching of physiology is preceded by experiments and observations by the student himself. In the old method the stress is upon didactic teaching; in the new there is less didactic teaching but the stress is on observation. This book is very much like some of the works on practical physiology published in this country but there is much less chemical physiology. The scope of the work will be best understood by stating that it gives an account of fundamental and accessory experiments in some fields of physiology. These are general properties of living tissues, methods of electrical stimulation, graphic method, electrical, chemical, and mechanical stimulation of nerve and muscle, and irritability and conductivity. The second part deals with the "income of energy" under the following heads: fermentation, blood, and respiration; while Part III. treats of the "outgo of energy." It comprises the consideration of animal heat, electrometric phenomena of muscle and nerve, the change of form of a contracting muscle, the central nervous system, skin, general sensations, taste, eye and vision, mechanics of respiration, circulation of the blood, and innervation of the heart and blood-vessels. The directions are clear, definite, and precise, while 74 illustrations help the student in the setting up his apparatus and arranging his experiments. Students preparing for the higher examinations will find it most helpful. This is the second edition and in its "final form" it will constitute "A Laboratory Text-book of Physiology."

JOURNALS AND MAGAZINES.

The Edinburgh Medical Journal.—In the January number of this journal Dr. W. Allan Jamieson records some interesting observations on rarer varieties of bullous affections of the skin—anomalous herpes zoster, dermatitis herpetiformis, pemphigus foliaceus and vegetans, and lichen planus with bullous lesions. An address by Dr. G. A. Gibson on Arterial Pressure emphasises the value of instrumental measurement of blood pressure, examples of which are to be seen in acute pneumonia and in aortic disease, wherein it is a useful guide to prognosis. Dr. J. S. Fowler writes on the "energy-quotient" in infant feeding, and Dr. D. Chalmers Watson on chronic arthritis, in which disease he holds that sufficient attention has not been paid to other organs besides the joints. A presidential address delivered before the Edinburgh Royal Medical Society by Dr. David M. Barcroft on Some Clinical Accessories deals pleasantly with the discoveries of the method of percussion, of the stethoscope, and of the sphygmograph.

The Scottish Medical and Surgical Journal.—The first number of the new year opens with a presidential address by Dr. A. Rudolph Galloway to the Aberdeen Medico-Chirurgical Society on the subject of Sight-testing and the drawbacks and dangers inherent in the prescribing of spectacles by opticians. A paper by Dr. Alexander Goodall and Miss Isabel Mitchell on the Physiological Action of the Formates may be commended to the study of those who have been impressed by some recent writings in praise of these drugs as stimulants. These authors find that the sodium and potassium salts are toxic, while the calcium salt may perhaps be useful as a soluble salt of lime in place of the chloride or lactate but not on account of its acid radicle. The sixth instalment of Dr. A. Dingwall Fordyce's studies on infant feeding deals with artificial substitutes for breast milk and among other things advocates the use of scalded rather than sterilised cows' milk.

The Bristol Medico-Chirurgical Journal.—In the December issue Dr. Henry Waldo writes on Syphilis in the light of recent investigations on the spirochæta (treponema pallidum). He supports the intermittent method of administering mercury which is in favour on the Continent. Mr. Ernest W. Hey Groves writes on Spinal Anæsthesia which he believes to be useful in certain special emergencies but not as a routine method; and Dr. F. Percy Elliott continues his paper on the Value of Compression of the Aorta in Post-Partum Hæmorrhage. A case of Generalised Sarcoma recorded by Dr. F. G. Bushnell was remarkable for the alterations in the blood, which showed a high degree of lymphocytosis (large lymphocytes, 37 per cent.; small, 29 per cent.), the polymorphonuclear cells only reaching 13 per cent. Dr. William Cotton pleads for uniformity in radiography to enable different observers to compare notes with some degree of accuracy.

THE HOSPITAL SATURDAY FUND.—Sir Savile B. Crossley presided at a special meeting of the board of delegates of the Hospital Saturday Fund Association on Jan. 18th at the offices, Gray's Inn-road, W.C. On the recommendation of the distribution committee it was decided that the sum of £24,708 0*s*. 2*d*. should be awarded to the 209 participating medical charities—namely, 33 general hospitals, £8258 5*s*; 16 cottage hospitals, £323 15*s*.; 75 special hospitals, £8416 12*s*.; 29 dispensaries, £818 16*s*.; 24 convalescent homes, £1483 17*s*.; 19 nursing institutions, £420 15*s*.; and 13 miscellaneous (including ambulance, distribution, and surgical appliance committees), £4986 0*s*. 2*d*. The total receipts for 1907 amounted to £27,168, as compared with £26,460 in 1906, an increase of £708.

a little below, the umbilicus might delay a correct diagnosis and had to be borne in mind. In three cases the symptoms so closely simulated perforated gastric ulcer that the duodenum and stomach were explored first and later the appendix. One patient was admitted to hospital as suffering from suppurative arthritis of the hip-joint, while in reality it was a large appendicular abscess extending below Poupart's ligament. If in a first attack an early diagnosis were made and an early operation performed the appendix could be removed through an incision planned to avoid the possibility of a ventral hernia; the acute symptoms rapidly subsided and the patient could be allowed up within a fortnight with the assurance of no subsequent attack. In such cases the prognosis was extremely good; of 14 cases so treated all recovered. If an abscess had developed the prognosis was rendered much more grave. The early local dangers were peritonitis, multiple abscesses, and obstruction, while the early general dangers were pyæmia and septicæmia. Even if the appendix were removed other abscesses might arise as well as fæcal fistula. Many patients were permanently disabled, though their lives had been saved by operation. The proper treatment for this disease was the removal of the appendix at the earliest possible moment. If a surgeon could not be readily obtained morphine should never be administered, but the patient should be put on starvation treatment with enemata of saline fluid for the first 24 hours, with the local application of heat or cold. If a patient recovered from an attack, no matter how mild, he ought to be operated upon. The mortality in interval operations was very small, while if performed within 24 hours in acute cases it might be as low as 0·5 per cent.—Mr. J. M. COTTERILL said that if the case were seen in the country then an operation should be performed at once and at any stage, but in town it was different. An operation performed within 20 hours of the onset was almost absolutely safe; if, however, two or three days had elapsed then it was better to wait and to perform the interval operation.—Dr. J. O. AFFLECK said that he had never been converted to the view that appendicitis was a disease only to be considered by the surgeon. He had seen healthy appendices removed because the symptoms had indicated appendicitis. Operation involved a risk to life and in his opinion it was best not to lay down any hard-and-fast rule but to weigh every case on its own merits.—Mr. CAIRD said that in the wards with which he had been connected there had been 174 interval operations in seven years with no deaths. Even in such cases there was a danger, however, and he had grown bacillus coli communis and a diphtheroid organism from the gelatinous matter covering over an old perforated appendix.—Mr. H. J. STILES said that if he were called at night and found a fulminating case he would operate at *once* and in acute cases always within 48 hours. The difficult cases were those seen for the first time two or three days after the onset; in such the surgeon's own experience must be the guide. A point which helped in diagnosis was the presence of fine crepitation in the subcutaneous tissue of the right iliac fossa. Among 52 acute cases he had had six deaths, or 11·5 per cent., and among 150 interval cases in two years he had one death.—Dr. D. O. A. MCCALLUM, Dr. G. LOVELL GULLAND, the PRESIDENT, and others also took part in the discussion.

Dr. FLEMING gave a demonstration of the Changes in the Optic Nerve in cases of Intracranial Tumour. He said that the marked hypertrophy and proliferation of the neuroglial cells in the optic nerve in these cases were different in some respects from what was seen in the neuroglial cells in the brains of cases of general paralysis of the insane. There was nuclear mitosis, often two or more nuclei being seen in one cell, and the cytoplasm in some of the cells lacked definite outline, resembling a condensation of fibrillæ in the neighbourhood of the original cell body. The processes became much thicker and more easily traced for a considerable distance from the parent cell. These changes were best marked in the orbital portion of the optic nerve, being most obvious at the periphery of the nerve near the pial sheath but were also seen throughout the whole of the nerve. They were not nearly so obvious in the optic tracts, although they were very characteristic in the neighbourhood of the tumour or tumours in the brain. Dr. Fleming considered that the limitation of these pathological changes depended on the great development of neuroglia, normally, in the orbital part of the optic nerve in contrast to the small number of these cells in the optic commissure and tracts. He noted in several cases a complete break in the continuity of the neuroglial hypertrophy between the optic nerves and the brain tissue near the tumour. The neuroglial changes were most satisfactorily demonstrated in cases of optic neuritis which were advancing to consecutive atrophy. He showed incidentally how the neuroglial hypertrophy brought into prominence the existence of other elements in the neuroglia which Dr. W. Ford Robertson had designated mesoglial cells. These cells might possibly increase in number to some extent in optic neuritis, but they did not undergo any hypertrophy. The neuroglial cells in primary and secondary atrophy of the optic nerve showed no hypertrophy at all comparable to that found in optic neuritis due to intracranial tumour. In tuberculous meningitis no optic neuritis occurred unless there were coexistent tumours in the brain substance. In neuroretinitis of renal origin similar neuroglial changes were found and closely resembled those seen in intracranial tumour. Dr. Fleming argued in favour of a toxic origin for the neuroglial changes in optic neuritis due to intracranial tumour. He considered that the hypertrophy of neuroglial cells was primary, although by that statement he did not intend to convey the idea that it constituted the only primary lesion. The lymph channels in the orbital portion of the optic nerve were more numerous than in the remaining part of the visual tract and this, together with the greater number of neuroglial cells histologically, might account for the position of the most marked neuroglial hypertrophy and proliferation.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

Exhibition of Specimens.

A MEETING of this section was held on Jan. 10th, Dr. A. R. PARSONS, the President, being in the chair.

Dr. HENRY T. BEWLEY exhibited specimens of Septic Endocarditis obtained from a man born in 1885. In 1898 he had suffered from rheumatic fever, being laid up for six months, and during the following three years he had further attacks. He went into hospital in February, 1905, suffering from breathlessness and palpitation. He was found to have a hypertrophied heart, double aortic disease, and mitral regurgitation. He was again admitted to hospital on Oct. 19th, 1907, and died on Dec. 16th. His last illness had begun in the previous June with feverishness, occasional sweatings, and loss of strength. While in hospital his evening temperature rose to 101° and 102° F., and his morning temperature varied from normal to 100°. The condition of the heart was much the same as before and sometimes a presystolic thrill was felt. The diagnosis was septic endocarditis. At the necropsy the heart was found very much enlarged and the pericardium was found to be universally adherent—a condition of which there was no clinical sign whatever. The right cavities of the heart were comparately small, the left ventricle was enormous, and both the mitral and aortic valves were festooned with soft pink vegetations. The kidneys were enlarged, the spleen was very much enlarged, and there was an abscess in connexion with an infarct in the spleen. Dr. W. G. Harvey made an examination of one of the vegetations, which showed enormous numbers of cocci of the streptococcus type. The case was therefore one of endocarditis, with an organism of extremely mild virulence; the sepsis had lasted fully six months.

Dr. R. TRAVERS SMITH gave the main clinical facts of a case of Intra-thoracic Tumour. The patient, a man, aged 56 years, was admitted to hospital on April 23rd, 1907, and died in about six weeks. A few months before admission he received a heavy blow on his chest, but it could not be said how much that had to do with the growth in his thorax. An effusion in the patient's right pleural sac accumulated rapidly and on tapping it they found that it had the character of a passive effusion, with poverty of albumin and cellular elements. He had to be tapped several times. Cyanosis was then very remarkable and he began to breathe with a slight stridor. About a week before his death he became very œdematous in his lower extremities, and some fluid formed in the peritoneum. One day he complained of violent pain in his right axilla and died six or seven hours afterwards from respiratory embarrassment. The disease was found to be a lymphosarcoma involving all the structures in the thorax. The whole of the superior vena cava was absolutely filled with it,

THE LANCET.

LONDON: SATURDAY, JANUARY 25, 1908.

The Treatment of Pulmonary Tuberculosis by Graduated Labour.

THE open-air or sanatorium treatment of pulmonary tuberculosis has now become generally recognised as a valuable therapeutic measure. First carried out under a regular system by Dr. BREHMER at Göbersdorf in Silesia, subsequently many institutions were founded upon his model, while various modifications in detail have been made by different physicians as has been recorded from time to time in our columns. All the developments of the treatment have not been in the same direction, and different opinions have prevailed as to the ideal environment of the tuberculous patient in a sanatorium, but we are only considering now the question of exercise. While some authorities attached great importance to rest in the open air, Dr. BREHMER considered that exercise, especially hill-climbing, was essential to the obtaining of the full value of this treatment, and Dr. WALTHER at Nordrach showed that excellent results could be obtained by graduated walking exercise, especially when, in suitable cases, this exercise was being pushed to the extent of walking 20 miles a day. Following upon the observations of the German physicians numerous sanatoriums have been established in this country, the essential principle being that the patient should live as much as possible in the open air but a certain amount of exercise was considered advisable. The sanatorium treatment has now entered upon a new phase and a most important one. At a meeting of the Medical Society of London held on Jan. 13th Dr. MARCUS S. PATERSON, the medical superintendent of the Brompton Hospital Sanatorium at Frimley, read a paper on Graduated Labour in Pulmonary Tuberculosis, which was supplemented by another on the Effect of Exercise on the Opsonic Index of Patients suffering from Pulmonary Tuberculosis by Dr. A. C. INMAN, the superintendent of the laboratories of the Brompton Hospital. These two papers are published in full in our present issue and upon being read were described by Dr. J. KINGSTON FOWLER, President of the Medical Society, as marking an epoch in the treatment of pulmonary tuberculosis.

Dr. PATERSON had observed that many tuberculous patients who had followed their ordinary occupations up to the time of admission to the hospital were in a very fair condition of health. It therefore occurred to him that if some tuberculous patients, being in adverse circumstances and without medical guidance, could act thus without apparent injury they ought, under ideal conditions and with the work carefully graduated in accordance with their physical state, to be able to undertake useful labour. Acting on this idea he has elaborated a system of graduated labour which not only carried out the intention of rendering the patients fit to return to their ordinary occupations on leaving the sanatorium but has proved a most valuable therapeutic measure in the treatment of pulmonary tuberculosis. In his paper he describes in detail the various grades of labour through which the patients are made to pass, together with the precautions which had to be observed in order to protect them from the harm which might ensue if too much effort was attempted. He also mentions the symptoms which suggest that the patients have overtaxed their physical resources. Those physicians who wish successfully to carry out this method of treatment will do well to study carefully Dr. PATERSON'S remarks, for it is on the care that is devoted to detail and on the loyal coöperation of the patient that the result of the treatment will depend. The patients who were sent to the Frimley sanatorium for treatment had all been for some time at the parent institution at Brompton. They were all carefully selected as regards the extent of the disease, the state of the temperature chart (no markedly febrile cases being despatched to the sanatorium), and the evidences which they exhibited of satisfactory resistance to the progress of the disease. When they reached the sanatorium the treatment by exercise was at once commenced. Every patient was informed that he would be treated by prescribed rest and exercise and that as he did not himself know the amount of each required he must do exactly as he was told. Absolute obedience to the orders of the physician in charge of the case was seen to be essential. Dr. PATERSON brings out two points in particular in his valuable paper: First, that special heed must be paid to the word "graduated" in arranging the amount and kind of work to be done by each patient; and secondly, that the effect of that work on each patient as shown by the temperature chart and other signs must be carefully watched. He describes in considerable detail how the labour is graduated at Frimley, while he concludes that if the patient's temperature remains above 99°F. in the case of men or 99·6° in the case of women the patient should be confined to bed, work should be prohibited, and reading should be the only recreation permitted. These two points, reinforced as they are by a record of practical experience, go far to demonstrate graduated labour to be a valuable form of treatment in pulmonary tuberculosis.

Dr. INMAN'S observations on the effect of exercise on the opsonic index of patients suffering from pulmonary tuberculosis corroborate Dr. PATERSON'S clinical results in a remarkable manner. In his paper he gives a brief review of Sir ALMROTH WRIGHT'S investigations and the principles of immunity enunciated by that observer. It has been shown "that auto-inoculations follow upon all active and passive movements which affect a focus of infection and upon all vascular changes which activate the lymph-stream in such a focus." It is by the agency of such auto-inoculations that nature achieves curative effects in bacterial infections. Dr. INMAN carried out his researches at the Brompton Hospital sanatorium in a most thorough and praiseworthy manner. He very wisely eliminated the personal element so far as possible, while he safeguarded himself from the possibility of a biased mind by conducting all his observations with unknown specimens of blood. These were obtained from the patients under the necessary conditions, of the lobules, with displacement eccentrically of the central vein. These changes were demonstrated also from livers showing subacute yellow atrophy and cirrhosis. This proliferative change in cirrhosis often went further and gave rise to the malignant epitheliomata of the liver seen in cirrhotic livers. In such tumours all stages of cell growth were seen, from the proliferative changes found in rupture to the most irregular forms of cells, many having very many nuclei. These tumours were often multiple and seemingly of the same age, so that the influences determining tumour growth in one part of the liver must have been effectual in determining such growth at another part. Professor Muir, in summing up, showed how this was comparable to multiple epitheliomata after psoriasis.

PATHOLOGICAL SOCIETY OF MANCHESTER.—A laboratory meeting of this society was held in the Pathological Department of the University on Jan. 15th at which the following specimens were shown. Dr. W. B. Anderton: Specimens recently added to the museum.—Dr. C. H. Melland: Microphotographs of the Blood in Various Conditions and Illustrations of the Methods of Staining Blood Films.—Dr. G. E. Loveday: Epithelial Odontomata.—Dr. F. Craven Moore: Specimens illustrating Morbid Conditions of the Stomach.—Dr. D. Orr and Dr. R. G. Rows: Specimens illustrating Morbid Lesions of the Central Nervous System, Natural and Experimental.—Miss Elsie M. Royle: Specimens from two cases of Leucocythæmia.—Dr. J. Lorrain Smith: Hæmolymph Glands.—Dr. Lorrain Smith and Dr. W. Mair: Specimens illustrating the Application of Weigert's Myelin Method of Staining.—Other specimens were shown by Dr. C. Powell White, Dr. N. J. H. Gavin, Mr. Wolstenholme, and Mr. Roberts.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE.—A meeting of this society was held on Jan. 17th, Sir Patrick Manson being in the chair.—Dr. W. Carnegie Brown, in an interesting biographical sketch of Professor Fritz Schaudinn, said that the great professor's life was lost as a direct result of his disastrous experiment of self-infection and it was more than probable that his health was undermined by his almost reckless industry, for Schaudinn would sit continuously for many days and nights following the life-cycles of a series of different organisms. Schaudinn won for himself in his short lifetime a reputation that in his own branch of science was altogether without parallel and he achieved this by his unwearying industry, by his marvellous facility of technique, by his phenomenal power of interpretation, and by his almost supernatural scientific "flair."—Dr. G. C. Low read a paper on the Unequal Distribution of Filariasis in the Tropics.

Reviews and Notices of Books.

Diseases of Women: A Clinical Guide to their Diagnosis and Treatment. By GEORGE ERNEST HERMAN, M.B. Lond., F.R.C.P. Lond., Consulting Obstetric Physician to the London Hospital. Third edition. With 265 Illustrations. London and Paris: Cassell and Co. 1907. Pp. 900. Price 25s.

THE more often we consult this work of Dr. Herman the more we are impressed with the excellence of the teaching it contains and the clearness of its style. Perhaps it does not appeal to the ordinary student so much as other books written more ostensibly for the purpose of enabling him to pass examinations, but as a safe guide to good treatment we know of no work on gynæcology in our language which is its equal. The third edition has now appeared and the author has revised carefully the whole work. He has made certain alterations and additions which tend to increase its value but it retains all the original features which distinguish it from most other text-books. The chief danger which besets the neophyte in the practice of gynæcology is the tendency to neglect the teachings of general medicine in his treatment of his patients. A careful reading of the first part of this book would go far to cure him of such a tendency but the best method of avoiding any such circumscribed view is to acquire a thorough grounding in general medicine before taking up a special branch. If such a course were pursued more frequently by intending specialists we should hear less of their narrow-mindedness as regards their particular "allotment of the body," as we have heard it called by a layman with little reverence for the present-day tendency to over-excessive specialisation.

In an endeavour to present a clear view of the exact nature of that important disease hysteria Dr. Herman has elaborated his account of this affection and has embodied in his chapter on the subject the modern conception of it as a disease characterised by definite physical signs. Written as this book is from the point of view of the clinician no mention was made in former editions of the pathological histology of the various diseases described. In view of the great importance of the recognition of cases of early carcinoma of the uterus by the aid of the microscope Dr. Herman has given a brief account of the appearances under the microscope of cancer of the uterus with some additional illustrations. And here perhaps we may be allowed to find some fault. Many of the illustrations are of interest from the historical aspect and some are exceedingly good in themselves, although they are badly reproduced and of old standing. On the other hand, many of the illustrations could readily be replaced by better ones, not only better examples of the different diseases which they are intended to illustrate, but also infinitely better examples from an artistic standpoint. We know Dr. Herman's appreciation and veneration for many of the masters of English gynæcology but we would venture to suggest that he should not allow his book to have its value diminished by the reproduction of so many poor and old drawings. The section dealing with the interesting disease of chorion-epithelioma has been considerably amplified and there are some most excellent illustrations in this case taken from the monograph of Dr. J. H. Teacher. The recent work of Dr. H. Williamson and Dr. W. H. Atlee on the Nature of Vascular Caruncles has also been incorporated in the chapter on Painful Micturition. We regret to see that in the chapter on Cancer of the Cervix the author still recommends bisection of the uterus in performing vaginal hysterectomy, a plan which we cannot but think faulty, in that it must increase the risk of implantation of the cancer cells.

The section on Abdominal Hysterectomy has been revised and brought up to date. We gather Dr. Herman thinks that for simple cases of fibroid tumours not involving the cervix subtotal hysterectomy is a sufficient and good operation, and that he would reserve pan-hysterectomy for growths which cannot for various reasons be treated by the former operation. We consider this is the common-sense view to take of the question; the mortality of the two operations at the present day is practically the same and the reasons which are brought forward by the adherents of the one or the other seem fairly equally balanced when regarded by the impartial observer.

This, in our opinion, is the best text-book of gynæcology in the English language. Written by a scientific physician from the clinical point of view its teaching is based on sound principles which have stood the test of practical experience.

Eye Injuries and Their Treatment. By A. MAITLAND RAMSAY, M.D. Glasg., Ophthalmic Surgeon, Glasgow Royal Infirmary; Professor of Ophthalmology, St. Mungo's College, &c. Glasgow: James Maclehose and Sons. 1907. Pp. 210. Price 18s. net.

IN bygone generations it was customary for the medical Chrysostoms of the day to publish their words of wisdom in the form of collected essays and clinical lectures. These were always ponderous and dignified, often *dogmatic*, as befitted *ex cathedrâ* statements; they were usually models of classical erudition and literary style, and sometimes they infant. In hospital practice an operation at this early age would almost certainly mean weaning but in private practice it need not do so. Should the child be weaned to allow of the performance of the operation it is essential that he or she should be allowed to become accustomed to the artificial food before being submitted to operation. In some cases it may be advisable to operate even before the fourth month, as when strangulation has occurred or has threatened, or when the hernia cannot be kept up by a truss. The operation itself has some peculiarities. The various tissues are more difficult to recognise than in the adult and the smallness of the structures also renders the operation difficult. To expose the deep inguinal ring the external oblique has to be divided for a short distance. When the sac is of the partial funicular form it is isolated and ligatured at the internal ring. When the sac is of the total funicular type it is divided where convenient and the upper portion is dealt with as already mentioned but no attempt is made to close the lower portion which is in connexion with the testis. In most cases the inguinal canal is closed by a couple of sutures which fasten the internal oblique to Poupart's ligament. The cut margins of the external oblique are united and the wound is closed. The results obtained have been good. No fatal case occurred; suppuration was present in six cases; in one of these the operation was done for strangulation and in several of the others there was some reason for the appearance of suppuration. It was not possible to see the after results in all cases but in those that could be traced the result was perfect, there being no recurrence in any case. We have devoted some space to a consideration of Mr. CLOGG'S article, for it embraces all the points of importance in a subject of widespread interest to the medical profession.

◆

The Medical Officer of the Local Government Board: a New Appointment.

THE announcement made at the end of last week that the post of Medical Officer of the Local Government Board had been relinquished by Mr. WILLIAM HENRY POWER and that Mr. JOHN BURNS had filled the vacancy by the appointment of Dr. ARTHUR NEWSHOLME has come somewhat unexpectedly. It was not generally realised that Mr. POWER had reached the age, 65 years, at which retirement from office follows under Civil Service rules; and his successor would have been looked for naturally among the many distinguished members of the medical staff of the Local Government Board. Dr. NEWSHOLME will bring to his new duties an ability and industry which are universally recognised and have been manifested in many fields of work, especially in his numerous contributions to vital statistics, the prevention of pulmonary tuberculosis, and domestic and educational hygiene. Many of these contributions have appeared in our pages, so that we know their value to the medical profession. He has presided over or organised with conspicuous success the work of many public health societies and congresses; he has edited *Public Health* and the *Journal of Hygiene*; for many years he has ably filled the office of medical officer of health of Brighton, and he has there trained many of the younger generation of health officers. The Government appointment, which he has been called upon to accept, may fairly be described as alike the highest and the most onerous of any in the public health service of the country and is as exacting as any Civil Service appointment of the first rank. We wish him success in his new vocation and are certain that he will find himself loyally served by those over whom he has been placed.

In his book "English Sanitary Institutions" Sir JOHN SIMON, the first man called to the office, has given an account of the beginning and subsequent progress of the service for which the Medical Officer of the Local Government Board is responsible. From these writings it is possible to form some estimate of the task which that officer has to undertake and of the difficulties with which he has to contend in striving for the advancement of sanitary science and of sound and well-considered methods of sanitary administration. Large conceptions of the part to be played by medical considerations, in the wider sense of the term, in the proper government of the country received little sympathy or practical encouragement from the Minister chiefly concerned with the early organisation of the Local Government Board. Even in comparatively simple matters of administration the initial constitution of that Board, with its multifarious detailed functions in connexion with Poor-law and other matters to which priority of attention was given, formed a dead weight against which SIMON decided that it was hopeless for him to strive—in fact, he has himself told us that he resigned because he considered himself defeated in his proper policy. In the leisure of after years, however, SIMON was able to bear testimony to the steady headway in many of the directions which he had advocated made by his successors, notably by Sir G. BUCHANAN, Sir R. THORNE-THORNE, and Mr. POWER. In part, no doubt, the increasing influence of successive medical officers has been a natural result of the way in which people have now come to demand measures to protect the public health and of the greater readiness of Ministers to see advantage in doing something, or in professing to do something, to meet this demand. But, on the other hand, the central administrative machine to which the chief medical adviser of the State is attached has continued year by year to take on new duties unconnected with public health and to add to its initial cumbrousness, while the reluctance of Ministers seriously to take up and to push through any bold or comprehensive scheme of public health administration or legislation which entails Parliamentary opposition has become more and more obvious in recent Parliaments. The Local Government Board and its medical department may properly be credited with much sanitary administrative work which is good so far as it goes, but it would be interesting to know how many schemes of constructive sanitary policy in matters both large and small, which have entailed endless inquiry and work by SIMON'S successors, could be unearthed from the Board's pigeon-holes.

It is more profitable to turn to that part of the work of the Medical Officer of the Local Government Board which is disclosed to the public in the series of annual volumes and special reports from the medical department. These volumes are systematically reviewed in our columns and are well known to all sanitarians. The Medical Officer has the duty of acting as expert adviser to certain other by the many elaborate illustrations with which it is provided and which have been exceedingly well reproduced. Many of them are from original drawings made by the author whose efficiency in this direction needs no further comment.

The Essential Similarity of Innocent and Malignant Tumours: a Study of Tumour Growth. By CHARLES W. CATHCART, M.A., M.B., C.M. Edin., F.R.C.S. Eng. and Edin., Surgeon, Royal Infirmary, Edinburgh; formerly Conservator of the Museum of the Royal College of Surgeons; Edinburgh. With 86 illustrations, for the most part photographic reproductions from specimens. London: Simpkin, Marshall, Hamilton, Kent, and Co., Limited. Bristol: John Wright and Co. 1907. Pp. 79 and 38 plates. Price 9s. 6d. net.

THE medical student is taught dogmatically that a new growth is either innocent or malignant but when he has attained sufficient knowledge to be able usefully to think for himself he finds that in practice this sharp distinction cannot always be maintained. Of two tumours, resembling each other closely histologically, one may lead an entirely innocent course and the other may show signs of malignancy. Moreover, a new growth may for many years have enlarged but slowly and yet suddenly its rate of growth may increase and other malignant manifestations may appear. Mr. Cathcart has written this book to call attention to these important facts and he advances many proofs that innocence and malignancy are merely the marks of the extremes of a long series of growths and that all intermediate stages occur. He considers it of importance that the idea of the essential similarity of innocent and malignant growths should be recognised, for, as he says, no theory of the causation of tumour growth can be satisfactory which does not apply equally to innocent and to malignant tumours and that no search for a cure for cancer is likely to be successful (unless by chance) so long as the search is directed by the theory that cancer is a disease by itself. Further, he claims that no type of tumour can be considered with respect to operative treatment to be necessarily exempt from the taint of malignancy. We agree with Mr. Cathcart in much that he maintains, though he seems to us to be a little inclined to generalise beyond the strength of the facts. It is true that in many classes of tumours all gradations occur between the purely simple and the very malignant, yet in other classes the distinction is much more clearly marked. It is early yet to dogmatise as to the exact relations of tumours; when we are acquainted with their true etiology we shall then, and not till then, be in a position to say exactly what is the real reason why one tumour is malignant and another not. We may mention that we quite agree with what Mr. Cathcart says as to the local recurrence of a tumour as a sign of malignancy. Any form of tumour will recur if part has been left behind; and recurrence is more likely to occur in malignant growths merely because it is difficult in such growths to define the limits of the original tumour. The book is well worth reading, for it emphasises portions of the pathology of tumours to which too little attention is generally paid.

A Manual of Clinical Diagnosis. By CHARLES E. SIMON, B.A., M.D., formerly of the Resident Staff of Johns Hopkins Hospital; Professor of Clinical Pathology at the Baltimore Medical College; Clinical Microscopist to the Union Protestant Infirmary. Sixth Edition, thoroughly revised. Illustrated with 177 engravings and 24 plates in colours. London: Henry Kimpton. Glasgow: Alexander Stenhouse. 1907. Pp. 682. Price 21s.

THIS work forms a manual of clinical diagnosis by means of microscopic and chemical methods for students, hospital physicians, and practitioners. The fact that it has reached the sixth edition sufficiently demonstrates that the efforts of the author have met with the success which they deserve in supplying a text-book dealing with the most modern aids to diagnosis. A large amount of work has been accomplished in this line of research since the last edition was published, but Dr. Simon has dealt with it in a most praiseworthy manner and by dint of careful revision has incorporated the new material without greatly enlarging the size of the volume. He states in the preface that every page has undergone a radical review so that all the most modern microscopic and chemical processes likely to assist in diagnosis have been included. The chapter on the examination of the blood has been brought fully up to date. The methods of counting the blood cells are fully described and the various varieties of leucocytes together with the deductions to be derived from observation of them are carefully considered.

The section dealing with parasites in the blood is capitally worked out and a large amount of valuable information is presented. A full account is given of the malaria organism and its cycle of development is explained. The latest researches on trypanosomiasis are included, reference being made to the successful efforts of Novy and McNeal to cultivate the parasite in artificial media. A good description is given of the spirochæta pallida, together with the methods which may be employed to demonstrate it in material obtained from syphilitic lesions. A chapter on opsonins has been introduced. Full details are given regarding the technique, which is necessarily rather involved, and a careful study of the directions should enable the reader to carry out the necessary processes. Dr. Simon has treated this subject with due caution but we consider that he has fairly presented the knowledge already obtained as regards the opsonic index.

Two appendices have been added. The first describes the methods of preparation of culture media and the second indicates the outline of a course in clinical laboratory methods. The latter is especially intended for post-graduate study. The whole work is excellently illustrated, the coloured plates being particularly well executed. We can cordially recommend this manual to our readers as containing trustworthy information on laboratory methods of diagnosis.

Diet in Health and Disease. By JULIUS FRIEDENWALD, M.D., Clinical Professor of Diseases of the Stomach in the College of Physicians and Surgeons, Baltimore; and JOHN RUHRÄH, M.D., Clinical Professor of Diseases of Children in the College of Physicians and Surgeons, Baltimore. Second edition, thoroughly revised and enlarged. London and Philadelphia: W. B. Saunders Company. 1906. Pp. 728. Price 18s. net.

THE second edition of this useful book has been improved by a few additions and minor changes but in its main features it is unaltered. The authors have evidently reviewed the literature of the subject with great care and have presented in a readable form various alternative diets adapted to many conditions. Where they give the recommendations of other authorities they usually quote extensively from the original papers. A valuable feature is that in cases where a definite diet is advised the heat values in calories are usually appended, or such data are given in tables as to allow those values to be calculated easily.

In our review of the previous edition we pointed out that the account given of the chemistry and physiology of digestion was a somewhat scanty one and in many ways hardly up to date. Although some alterations have been made it is still hardly worthy of the rest of the work. The various classes of food substances are considered in some detail and very full tables of their analysis are given; their digestibility and use as foods are also carefully described. The important work of Chittenden in regard to protein metabolism is quoted and its applications are discussed. The section dealing with medical work by the public. He dwelt also upon the remedies which might be applied to conditions which all must deplore and laid his chief stress upon a higher standard of medical education and examination, to be controlled by the State, and upon a recognition of the fact that medical services, which were formerly rendered chiefly or exclusively to individuals suffering from disease or accident, will for the future in constantly increasing proportion be rendered to the public for the prevention of illness rather than for its cure. He called attention to the example set by Harvard University in refusing its medical qualifications to students who had not graduated in Arts and set aside the question of any individual grievances thence arising as being absolutely unimportant when compared with the consequent elevation of the medical calling. It would, he declared, be an iniquity to keep a whole profession in suffering by widening the portals for one or two, otherwise able, who happen to lack aptitude for drawing, for spelling, or for Greek, or who have been misguided in their early education; and he is evidently of opinion that the necessary standards can only be maintained and the necessary restrictions enforced by taking the business of examination out of the hands of competing corporations and by committing it to the State. We cannot leave the pamphlet without calling attention to the *curiosa felicitas* of its concluding sentence. Dr. Ewart says of Thomas Young, one of the great worthies of the school of St. George's, that he "counted the waves of ether and made the Pharaohs speak."

THE ADMINISTRATION OF THE INFANT LIFE PROTECTION ACT.

AT the time of the enactment of the amended Infant Life Protection Bill of 1897, which came into operation in the following year, we wrote[1]: "Excellent as its provisions are, their value is materially diminished by defects in the Act which must very seriously diminish its utility. One of these consists in the exclusion of single nurse children from the Act, the other is the exemption of children for whose maintenance a sum exceeding £20 has been paid. The effect of these omissions is obvious. .... The unregistered crèche if broken up into its constituent units may still continue to flourish unobserved by the eye of authority. Nurse children, as is well known, are usually illegitimate. They are, as a rule, not desired by their parents. If they should be committed to the keeping of unscrupulous persons one by one, the law is no longer responsible for their safety, which must therefore be at best an unknown quantity." The opinion which we thus strongly expressed has not lacked support, as is shown by the fact that a further Amendment Bill has been introduced and obstructed in the House of Commons in each year since 1901. Meanwhile evidence of the urgency of the amendments continues to accumulate. Such a piece of evidence is before us in the shape of the tenth annual report of Miss Frances Zanetti who is inspector under the Act to the Chorlton union. She had made visits to various cases in which a single child was being reared by foster-parents for a small weekly payment. This she had little difficulty in doing where the child was being properly looked after, although the foster-parents knew that she had no legal right of entry. Where her visits were unwelcome she invariably found that there was something suspicious about the case. Two of the cases which she visited under the Act were sufficiently serious to be reported to the National Society for the Prevention of Cruelty to Children. One of these was of a terrible nature—that of a wasted baby who was found to be the fourth illegitimate child of a mother, 22 years old, who had been taken home intoxicated the night before the baby was born, and since its removal to hospital had been sent to prison for six months for prostitution. It seems a moot point whether an asylum for the insane would not be a more suitable place for this poor creature. Miss Zanetti gives an analysis of 21 cases which she visited under the Act, in which 54 children were being tended by foster-parents for sums ranging from about 3*s.* to 7*s.* weekly. Besides these she visited 43 cases which did not come within the provisions of the Act. We hope that many more inspectors take so liberal a view of their duties but it ought not to be left to the good-will of these officers and the consent of the foster-parents for "one child" cases to be visited. It is satisfactory to record that a deputation to the Home Office of the Poor Law Unions' Association has been informed by Mr. Herbert Samuel, M.P., that the amendment of the Infant Life Protection Act is to be included in the "Children's Bill" which is to be introduced next session. In a matter of common humanity, such as this is undoubtedly, we trust that it will be found possible to bury the party hatchet for the short space of time that would be required to pass it into the statute book. The sacrifice of Bills framed in the urgent interest of national hygiene to the idol of party feuds takes place with monotonous regularity—we need only instance the smothering of the Pure Milk Bill of 1907—but when it is a matter of the safeguarding of young children against cruelty and what may almost amount to slow murder by neglect we fancy most politicians would seek to alter the law if they were thoroughly aware of the evils which its present imperfect state tacitly allows.

TEMPORARY GASTROSTOMY IN THE TREATMENT OF PERFORATION OF THE STOMACH AND DUODENUM.

IN the *Northumberland and Durham Medical Journal* for December last Mr. W. G. Richardson has described an ingenious modification of the treatment of perforation of the stomach or duodenum in cases usually considered hopeless. If perforation of a gastric or duodenal ulcer occurs the peritoneal cavity is generally flooded with the contents of the stomach and death will follow if the patient is not relieved by operation. When the patient has recovered from the shock there is, as Mr. Richardson points out, a good prospect of recovery if an operation be performed within from six to nine hours, but after nine hours the prospect is almost hopeless. In the latter class of cases the patients are nearly dead when seen by the surgeon. The usual treatment is to open the abdomen, suture the perforation, and thoroughly wash out and close the abdomen. Sometimes drainage-tubes are placed in the flanks and pelvis. After the operation thirst is insatiable and is allayed by giving sips of water, generally warm. Nutriment is supplied in the form of enemata. Four years ago Mr. Richardson adopted the following method. If the perforation is on the anterior surface of the stomach he passes a large indiarubber catheter through it and secures the catheter in position by a surrounding purse-string suture. The catheter is passed carefully into the cardiac portion of the stomach—a point of great importance, as otherwise the stomach cannot be emptied. The operation is completed in the ordinary manner, with the exception that the stomach is sewn to the incision in the middle line as in a case of gastrostomy. Before the patient leaves the table his stomach is washed out with hot bicarbonate of sodium solution by placing a funnel in the end of the catheter and pouring in the solution. When nearly a pint has been introduced the funnel is lowered over the patient's side and the fluid siphons out. This is repeated until the fluid returns quite clear. After being put to bed the patient begins to cry out for water and is allowed to take it in large quantities. Mr. Richardson gives cold water because it is this alone for

New Inventions.

A TRUSS BELT FOR MOBILE OR FLOATING KIDNEY.

IN a paper on Mobile Kidney published in THE LANCET of August 3rd, 1907, p. 283, Mr. E. Stanmore Bishop said that his experience of the use of trusses, belts, or corsets in this condition was not altogether favourable but he mentioned the appliance manufactured for that purpose by Salt and Co. of Birmingham as being perhaps among the best. This firm has now sent us one of its truss belts for mobile kidney in which there is an alteration from the earlier patterns. The belt is made of a stout grey fabric, completely encircles the waist, and, as shown in the illustration, is fastened with three buckles. Inside there is a pocket containing a removeable indiarubber air-pad for the purpose of making pressure where required. The recent alteration already referred to consists in the addition of a specially constructed steel spring device fixed immediately over the air-pad, by which it is claimed that a more regular and correct pressure is obtainable than with earlier patterns of the appliance.

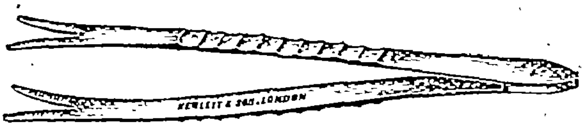
A NEW MERCURY INTERRUPTER FOR X RAY WORK.

FOR the greater part of the work done with an induction coil as a source of energy it is felt by most of those engaged in this line of investigation that some form of break employing mercury is probably the best to use. First came those in which a wire or blade was made to dip in and out of a vessel containing mercury. These were a great improvement on the platinum break and so long as workers were content to use voltages not exceeding 24 very good results were obtained with the coils then in use. Owing to the almost universal desire to use the current from the street mains directly for coils and also to their higher and increasing voltage interrupters of new design became necessary and these were all constructed upon a common principle—viz., a jet of mercury impinging upon a metal blade. In some the jet itself revolves and in others the jet is stationary while the blade or blades revolve around but close to it—all this taking place under the surface of a liquid dielectric, such as alcohol or petroleum, or in an atmosphere of hydrogen or coal gas. Except in the latter case there was, of course, great churning up of mercury and liquid dielectric which militated against good contact between jet and blade, and this was still further interfered with as time went on by the emulsification of the mercury which always took place sooner or later. For these reasons the output of a coil working with a mercury jet break is always more or less limited, which limit becomes lower and lower as the mercury becomes emulsified and dirty.

The Sanitas Electrical Company of 61, New Cavendish-street, W., has lately brought out a mercury break which possesses many advantages. It is driven by an electric motor which is placed at the bottom of the instrument with its shaft in an upright position. Upon the end of this shaft is mounted a hollow iron container—of about the size and shape of a small ginger jar—which revolves with it. This container, being of larger diameter at the middle than elsewhere and having a certain quantity of mercury and petroleum placed therein it follows that if it be rapidly rotated the mercury, &c., will rise so as to occupy the largest diameter of the jar, the mercury as the heavier liquid lying against the wall of the jar as a continuous band. Inside the container on a level with its equator is mounted a disc of fibre revolving freely on a vertical axis, which can be moved nearer or further from the wall of the container, and having two or more metal segments. This disc is so adjusted that its periphery is slightly imbedded in the mercurial band and contact is made and broken as the metal segments of the disc enter and leave the mercury, the disc being driven around by the mercury itself. The face of the metal contact piece is broad and contact is positive owing to the metal being plunged into the mercury, and as the speed is necessarily high the "break" is sudden and complete. Apparently there is little or no tendency for the mercury to become either dirty or emulsified. The contents of one interrupter which we examined after several hours' use were found to be perfectly clean. In practical use the output of the coil is under the most perfect control and can be varied from a short thin spark to a long and almost continuous ribbon resembling that obtained with an electrolytic interrupter but with a smaller consumption of current. Whether it will take the place of the electrolytic break is not yet certain but there is no doubt that this new form is a great advance on the other mercury breaks hitherto available.

BI-PRONGED FORCEPS.

MR. S. Gerald Gomes, F.R.C.S. Edin., of Tokio, Japan, writes: "I have designed for use with Reverdin's needle a pair of bi-pronged forceps which have proved very successful. For several years I have used Reverdin's needle and other simpler patterns and felt the want of a better means than the two hands of an assistant to carry the suture down to the slot in these needles, especially in deep and awkwardly placed wounds in the abdomen. After some experience with the forceps I find that the above-mentioned difficulties are obviated by its use. Moreover, it can also be effectively used in place of the ordinary dissecting forceps and wherever the usual pattern forceps are required. The instrument has been made for me by Messrs. C. J. Hewlett and Son, 35-42, Charlotte-street, London, E.C."



UNIVERSITY OF OXFORD: RADCLIFFE TRAVELLING FELLOWSHIP, 1908.—An examination for a Fellowship of the annual value of £200, and tenable for three years, will be held during the present term, commencing on Tuesday, Feb. 25th. Candidates must have passed all the examinations required by the University for the degree of Bachelor of Arts and for the degree of Bachelor of Medicine. They must not have exceeded four years from the time of passing the last examination required for the degree of Bachelor of Medicine. The successful candidate must before election declare that he intends to devote himself during the period of his tenure of the Fellowship to the study of Medical Science and to travel abroad with a view to that study. The Regius Professor of Medicine and the examiners, two months before the expiration of the second year after the election of each Fellow, present a report on the work done by him to the electors who may, if they think the report unsatisfactory, declare the Fellowship forfeited. The examination will occupy four days. Papers will be set in physiology, pathology, and preventive medicine, and a subject will be proposed for an essay. There will also be a practical examination in pathology. Any candidate desiring to offer in addition a special branch of either medicine or surgery must send notice of this to the Regius Professor of Medicine. All intending candidates should send their names, addresses, qualifications, &c., to the "Regius Professor of Medicine, University Museum," on or before Saturday, Feb. 8th.

medical work by the public. He dwelt also upon the remedies which might be applied to conditions which all must deplore and laid his chief stress upon a higher standard of medical education and examination, to be controlled by the State, and upon a recognition of the fact that medical services, which were formerly rendered chiefly or exclusively to individuals suffering from disease or accident; will for the future in constantly increasing proportion be rendered to the public for the prevention of illness rather than for its cure. He called attention to the example set by Harvard University in refusing its medical qualifications to students who had not graduated in Arts and set aside the question of any individual grievances thence arising as being absolutely unimportant when compared with the consequent elevation of the medical calling. It would, he declared, be an iniquity to keep a whole profession in suffering by widening the portals for one or two, otherwise able, who happen to lack aptitude for drawing, for spelling, or for Greek, or who have been misguided in their early education; and he is evidently of opinion that the necessary standards can only be maintained and the necessary restrictions enforced by taking the business of examination out of the hands of competing corporations and by committing it to the State. We cannot leave the pamphlet without calling attention to the *curiosa felicitas* of its concluding sentence. Dr. Ewart says of Thomas Young, one of the great worthies of the school of St. George's, that he "counted the waves of ether and made the Pharaohs speak."

THE ADMINISTRATION OF THE INFANT LIFE PROTECTION ACT.

AT the time of the enactment of the amended Infant Life Protection Bill of 1897, which came into operation in the following year, we wrote[1]: "Excellent as its provisions are, their value is materially diminished by defects in the Act which must very seriously diminish its utility. One of these consists in the exclusion of single nurse children from the Act, the other is the exemption of children for whose maintenance a sum exceeding £20 has been paid. The effect of these omissions is obvious. .... The unregistered crèche if broken up into its constituent units may still continue to flourish unobserved by the eye of authority. Nurse children, as is well known, are usually illegitimate. They are, as a rule, not desired by their parents. If they should be committed to the keeping of unscrupulous persons one by one, the law is no longer responsible for their safety, which must therefore be at best an unknown quantity." The opinion which we thus strongly expressed has not lacked support, as is shown by the fact that a further Amendment Bill has been introduced and obstructed in the House of Commons in each year since 1901. Meanwhile evidence of the urgency of the amendments continues to accumulate. Such a piece of evidence is before us in the shape of the tenth annual report of Miss Frances Zanetti who is inspector under the Act to the Chorlton union. She had made visits to various cases in which a single child was being reared by foster-parents for a small weekly payment. This she had little difficulty in doing where the child was being properly looked after, although the foster-parents knew that she had no legal right of entry. Where her visits were unwelcome she invariably found that there was something suspicious about the case. Two of the cases which she visited under the Act were sufficiently serious to be reported to the National Society for the Prevention of Cruelty to Children. One of these was of a terrible nature—that of a wasted baby who was found to be the fourth illegitimate child of a mother, 22 years old, who had been taken home intoxicated the night before the baby was born, and since its removal to hospital had been sent to prison for six months for prostitution. It seems a moot point whether an asylum for the insane would not be a more suitable place for this poor creature. Miss Zanetti gives an analysis of 21 cases which she visited under the Act, in which 54 children were being tended by foster-parents for sums ranging from about 3*s.* to 7*s.* weekly. Besides these she visited 43 cases which did not come within the provisions of the Act. We hope that many more inspectors take so liberal a view of their duties but it ought not to be left to the good-will of these officers and the consent of the foster-parents for "one child" cases to be visited. It is satisfactory to record that a deputation to the Home Office of the Poor Law Unions' Association has been informed by Mr. Herbert Samuel, M.P., that the amendment of the Infant Life Protection Act is to be included in the "Children's Bill" which is to be introduced next session. In a matter of common humanity, such as this is undoubtedly, we trust that it will be found possible to bury the party hatchet for the short space of time that would be required to pass it into the statute book. The sacrifice of Bills framed in the urgent interest of national hygiene to the idol of party feuds takes place with monotonous regularity—we need only instance the smothering of the Pure Milk Bill of 1907—but when it is a matter of the safeguarding of young children against cruelty and what may almost amount to slow murder by neglect we fancy most politicians would seek to alter the law if they were thoroughly aware of the evils which its present imperfect state tacitly allows.

TEMPORARY GASTROSTOMY IN THE TREATMENT OF PERFORATION OF THE STOMACH AND DUODENUM.

IN the *Northumberland and Durham Medical Journal* for December last Mr. W. G. Richardson has described an ingenious modification of the treatment of perforation of the stomach or duodenum in cases usually considered hopeless. If perforation of a gastric or duodenal ulcer occurs the peritoneal cavity is generally flooded with the contents of the stomach and death will follow if the patient is not relieved by operation. When the patient has recovered from the shock there is, as Mr. Richardson points out, a good prospect of recovery if an operation be performed within from six to nine hours, but after nine hours the prospect is almost hopeless. In the latter class of cases the patients are nearly dead when seen by the surgeon. The usual treatment is to open the abdomen, suture the perforation, and thoroughly wash out and close the abdomen. Sometimes drainage-tubes are placed in the flanks and pelvis. After the operation thirst is insatiable and is allayed by giving sips of water, generally warm. Nutriment is supplied in the form of enemata. Four years ago Mr. Richardson adopted the following method. If the perforation is on the anterior surface of the stomach he passes a large indiarubber catheter through it and secures the catheter in position by a surrounding purse-string suture. The catheter is passed carefully into the cardiac portion of the stomach—a point of great importance, as otherwise the stomach cannot be emptied. The operation is completed in the ordinary manner, with the exception that the stomach is sewn to the incision in the middle line as in a case of gastrostomy. Before the patient leaves the table his stomach is washed out with hot bicarbonate of sodium solution by placing a funnel in the end of the catheter and pouring in the solution. When nearly a pint has been introduced the funnel is lowered over the patient's side and the fluid siphons out. This is repeated until the fluid returns quite clear. After being put to bed the patient begins to cry out for water and is allowed to take it in large quantities. Mr. Richardson gives cold water because it is this alone for but to the experimenter they were simply numbered specimens; he never knew which patient's blood he was examining, a fact which adds a distinct value to the experiments. Dr. INMAN'S charts will be seen to correspond in a most remarkable manner with the progress made by the patients and we commend a careful perusal of his paper to our readers. The practical outcome of his investigations is well expressed by Dr. INMAN at the end of his paper. He points out that the opsonic index has shown that the exercise supplies the stimulus needed to induce artificial auto-inoculation, and that the systematic graduation of the exercise has regulated the dose both in time and amount. Further, Dr. PATERSON and Dr. INMAN are agreed that with the aid of the opsonic index the stimulus can be regulated with scientific accuracy, so that the treatment can be carried out more certainly and more rapidly. *In short, the results of these observations, both from the clinical and scientific points of view,* have demonstrated that the treatment of pulmonary tuberculosis by graduated labour is successful and founded on sound principles. Hitherto it has been assumed that the open-air or sanatorium treatment of this disease produces its results by improving the general condition and that life in the open air was the most important element in the therapeutics. Now it is more than suggested that although plenty of fresh air is absolutely essential for complete arrest, it is necessary that a series of auto-inoculations should be produced, and that the safest and most ready method of achieving the necessary dosage is graduated labour. This graduated labour has to be supervised very carefully or harm may result; the amount of exercise and work accomplished must be prescribed as carefully by the physician as any combination of drugs. The results of graduated labour in cases of pulmonary tuberculosis when more generally adopted will be watched with interest, meanwhile Dr. PATERSON is to be congratulated on having introduced the method of treatment and Dr. INMAN on the careful work that supplies the scientific corroboration.

---

[1] THE LANCET, Sept. 11th, 1897, p. 675.

Inguinal Hernia in Children.

IN the September number of the *Practitioner* appeared a paper by Mr. H. S. CLOGG containing an account of inguinal hernia in children and as it was based on 126 cases which had been submitted to operation the conclusions drawn are likely to be of interest and value. Mr. CLOGG has never met with what is called direct inguinal hernia in a child and all statistics show that it is intensely rare before puberty, so that it may be taken that inguinal hernia in a child means an oblique hernia. In regard to the question as to the relative frequency of the congenital and acquired forms of inguinal hernia in children the answer is definite. For the production of an acquired hernia some weakness of the abdominal wall is essential but in children there is practically always a ready formed sac supplied by the unobliterated processus vaginalis. Nearly all cases of inguinal hernia in children are of the congenital variety and this is so quite apart from the age of the child, for the sac is congenital even though it may not have been occupied by bowel until shortly before examination. The classification of congenital inguinal hernia which Mr. CLOGG prefers is undoubtedly the best; it divides these herniæ into the total funicular herniæ, in which the whole of the funicular process or processus vaginalis is patent, and those in which the funicular process is partly closed; these are partial funicular herniæ. Of Mr. CLOGG'S 126 cases 115 were in males and of these only 11 were cases of total funicular herniæ, that is, about 10 per cent.

The diagnosis of inguinal hernia in the child seldom presents any difficulty. A swelling in the groin, reducible on pressure, growing tense when the child cries, and often disappearing during sleep, can hardly be anything but a hernia, though occasionally a collection of fluid in a patent processus vaginalis with a very small opening at the internal ring may be mistaken for a hernia. There is another error in diagnosis which may prove of some importance. It is often thought that the only scrotal swelling which is translucent is a hydrocele but in young children where there is no large amount of fat and the bowel wall is thin an inguinal hernia may be translucent and thus it may be mistaken for a hydrocele. If on the strength of this mistaken diagnosis the swelling should be punctured with a trocar and cannula the result would probably be disastrous. The correct diagnosis having been made the question of the most suitable treatment has to be decided. There is a very widespread opinion that circumcision is of some value in the treatment of inguinal hernia in children. We quite agree with Mr. CLOGG that it cannot have the slightest effect in curing a hernia, though a tight phimosis may have assisted in the original descent of the bowel. As to trusses, it is doubtful how often a real "cure" of a hernia is brought about by a truss. The fact that a hernia has not been noticed for some months or years is no evidence that it has been really "cured"; for a perfect cure there must be an absolute obliteration of the sac. Now, the use of a truss may occasionally in very young children lead to the completion of the closure of the processus vaginalis when the closure has only been delayed, but when several months have passed since birth the probability of the obliteration of the sac by means of the pressure of a truss is very small indeed. Even in young infants when a truss is employed, should the bowel only come down once the benefit of the use of the truss for weeks may be destroyed and all chance of a real cure of the hernia be removed. Even when the employment of a truss does result in the permanent disappearance of the hernia with complete obliteration of the sac it is probable, as Mr. CLOGG suggests, that the truss takes no active part in the closure of the sac but merely permits that closure by preventing the descent of the bowel. For the past three years he has abandoned the use of a truss for inguinal hernia in children except in special cases, and even when he uses a truss he always warns the parents "that the truss will not cure the rupture." He holds that if a hernia has been seen after the first few weeks of life the only cure is by operation.

If, then, an operation is essential for all but the very early cases the question arises, At what age should it be done? Mr. CLOGG'S answer is that the earlier these cases are operated upon the better; he maintains that infants after the third or fourth month bear the operation well and make a very satisfactory recovery from it, and this is the age at which he recommends it unless it entails weaning of the

Skoda and Oppolzer, both great men, are placed in a certain antithesis to one another: the former as a great thinker and pioneer, the latter as a fascinating personality and a successful practitioner; the one teaching the student to observe and to think, the other to apply his knowledge practically. Oppolzer's clinic was a favourite resort for the students; he seems to have been a highly instructive teacher. A great impressionist, he observed rapidly and arranged his facts with the utmost certainty. He was, moreover, extremely fertile in suggestions for treatment. Professor Benedikt describes also his experiences at the wars, and his subsequent appointment at Vienna, his work upon electro-therapeutics, upon the medico-legal relations of insanity, and upon ophthalmology and diseases of the nervous system. He travelled in Italy, Sicily, France, Turkey, Russia, Scandinavia, Holland, Spain, and Great Britain, and of all the places he visited he has much of interest to relate. Of Great Britain he seems to retain most pleasant memories and he confesses that his preconceived notions of our country and ourselves he had to modify after his visits. Our great national collections filled him with wonder and admiration. For our various monuments and fountains in public places he has much praise and he mentions in particular the Albert Memorial in London, the Walter Scott monument in Edinburgh, that of O'Connell in Dublin, and the Knox statue in Glasgow. He acquits us of the hypocrisy with which continental nations are fond of accusing us. He commends the English manner of writing scientific papers and confesses to having taken Faraday as his model. He thinks that English scientific men can differ with less rancour than those of some other nations and that they are more inclined to wait for evidence before embracing novelties. Professor Benedikt's book is written in an easy, chatty style and makes most interesting reading. He is evidently a man of strong opinions, but sincere and earnest, and can point to a life of good and active work.

THE BARNSLEY DISASTER.

A HEARTRENDING catastrophe occurred on Jan. 11th at Barnsley, resulting in the death of 16 young children. The Public Hall, Barnsley, had been rented by the World's Kinematograph Company for a series of entertainments and a special matinée had been arranged for Saturday, Jan. 11th, at very low rates of admission, the charge for a gallery ticket being only *1d.* Apparently over 1000 persons, nearly all children, applied for admission to the gallery, the seating accommodation of which is 400 adults. When some 433 children had been admitted and children were still mounting the stairs some one apparently at the top of the stairs turned the children back and they were given the idea that they would be admitted to the pit. The children thus trying to descend the stairs got jammed with those trying to come up, some of them fell, and in a few moments there was a heap of struggling children. As a result 16 were killed and some 30 others more or less seriously injured. At the inquest, which was concluded on Jan. 17th, the jury found that the children were suffocated through negligence in not providing sufficient staff to regulate the children on the staircase, this resulting in a stampede of children on their being turned back. The foreman added that the jury did not think the negligence criminal or that the construction of the staircase was in any way answerable. There is no need to insist upon the horror which such a disaster inspires. It is a comfort to know that the construction of the staircase does not seem to have been faulty and the blame, if blame can be attributed to anyone, must lie first with those who seem to have allowed their children to go without proper escort, and secondly with the authorities of the entertainment in not seeing that there were sufficient persons to regulate the entry of would-be sightseers. Of the 16 children who were killed 10 were under seven years of age, the eldest was only 11 years old, and the youngest was four. Apparently most of the children who went to the show were in charge of other children aged as a rule about 12 or 13 years, and at least two of the children who were killed were in charge of other children aged 12 years. We are quite aware of the difficulty which the working classes experience in looking after their houses and their children too. Mere babies may be seen any day of the week wandering about the London streets and in and out of the traffic, and it is a perpetual marvel that there are not more lives lost than there are. But if the sad occurrence upon which we write will bring home the responsibilities to those who have the charge of children the 16 little Barnsley victims will not have yielded their lives in vain.

DISSEMINATION OF ENTERIC FEVER DUE TO A "TYPHOID CARRIER."

FOR several months medical authorities have been puzzled by outbreaks of enteric fever in a large institution on the outskirts of Bristol—the Brentry Home for Inebriates. 28 cases have arisen and the circumstances have been so peculiar that the medical officer of health of Bristol, Dr. D. S. Davies, suspected that the cause of the infection must be an unsuspected "bacillus carrier" capable of conveying infection to others though not suffering from the disease. His view has been justified by investigation, the source of the repeated attacks at Brentry having been traced to a woman in the institution who has not recently suffered from enteric fever but who has shown herself an effective disseminator of the typhoid bacillus. To the Bristol health committee recently Dr. Davies made a special report on the case. It is as follows:—

> In consequence of a continuing outbreak of enteric fever at this institution, which led to 28 cases and two deaths between September, 1906, and November, 1907, and as the infection was being introduced into the Bristol district, and part of the institution is within the city, I took up the investigation of the cause in November, as every effort on ordinary lines up to that time had failed to account for, or to stop, the spread of the disease. As I advised the chairman on Nov. 13th, the circumstances, judged from quite recent pathological work in Germany, seemed to me to point to the existence of a "carrier" case of chronic typhoid who was intermittently but unconsciously infecting the food or milk. Acting in conjunction with the Home Office medical inspector, I instituted a special pathological inquiry into the condition of certain inmates, and late in December the inquiry proved that one of those to whom the circumstantial evidence had pointed was undoubtedly a typhoid "carrier." This case had been tentatively isolated on Nov. 13th and I ventured to predict that no further cases would occur beyond the next incubation period. The last case was on Nov. 24th, and from then till now the institution has remained free. This new chapter in the history of typhoid infection is of immense importance, as we now have the key to many of these intermittent or dropping outbreaks which have hitherto defied explanation. Beyond the German cases, one in New York and one in Scotland, I am unaware of any other successful investigation of typhoid outbreaks on this line of research.

Mr. O. Wintle, the chairman of the health committee, congratulated Dr. Davies on his success in making this important discovery, and Dr. Davies, in reply, said that the matter was engaging the attention of a special department of the Local Government Board. The discovery that a certain proportion of those who have suffered from enteric fever may continue to harbour bacilli and to discharge them intermittently from the body long after the actual convalescence is one of great importance in regard to the spread of the disease, since it has now been definitely proved that such cases may be the unsuspected sources of widespread infection. The recognition and adequate treatment of such persons, to whom the name of "typhoid carriers" has been applied, is obviously a matter of great practical importance. A considerable amount of research has been carried out on this subject in Strasburg under the auspices of the German Imperial Board of Health by Kayser,[1] to whom is due the departments of State, notably in connexion with foreign and colonial affairs. The department supervises, by inspections at English ports and otherwise, the system of dealing with exotic diseases, such as cholera and plague, and the work done has brought much credit to British administration abroad and has enabled British representatives to take an important position in successive international sanitary conferences. It is hardly necessary to refer to the results of special inquiries made by the department year by year into conditions of disease prevalence throughout the country; the Medical Officer's publications may be said to have contained many, if not most, of the principal contributions which have been made to the modern science of preventive medicine in England. The work published in these reports under the heading of "auxiliary scientific investigations" comprises bacteriological, physical, and chemical inquiries of a very high order, usually on subjects requiring prolonged research of the sort which would hardly be attempted by anyone in the absence of the facilities given by the department. Present knowledge of, among other things, the bacteriology of scarlet fever and streptococcal infections, of the production of lead poisoning by moorland water-supplies, of the bacteriology of polluted soil, and of the penetration of disinfectant gases, for example, is largely based on these investigations. Many other examples could, of course, be given from the publications of the Medical Department of the Local Government Board and all would show the high standard of scientific and administrative work of the department, which during the last eight years has been fully maintained by Mr. POWER in his capacity of medical officer. It is now nearly 30 years since Mr. POWER, as an inspector of the Board, began the brilliant series of investigations regarding the spread of different infectious diseases which have since become classic. Long before his appointment to the principal post he had already undertaken the direction of the "field work" and auxiliary scientific investigations of his department. His judgment and sound scientific insight have been always freely put at the disposal of all who wished to consult him. His late chief, Sir R. THORNE-THORNE, described him as the "greatest living epidemiologist" and we know no one likely to dispute the title. At the end of his official activities and of the administrative career of the strong man who has "done his work and held his peace," Mr. POWER can look back on services to science and to the State which it is given to few men in any country to achieve.

◆

TUCKER v. WAKLEY AND ANOTHER.

THE action brought by Mr. AUGUSTUS Q. TUCKER against THE LANCET resulted in damages of £1000 being given to the plaintiff. A stay of execution was granted. Many matters of the first importance affecting as much the public as the medical profession were touched upon in the course of the four days' trial, and we shall probably consider it our duty to publish a full report of the case.

BRISTOL ROYAL INFIRMARY.—It has been proposed to endow a bed in the Bristol Royal Infirmary to the memory of the late Mr. C. J. King, a well-known Bristol merchant. The sum required is £1200 and of this amount £929 have been already received.

Annotations.

"Ne quid nimis."

THE ADMISSION OF WOMEN TO THE EXAMINATIONS OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AND THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE proceedings at the Extraordinary Comitia of the Royal College of Physicians of London held on Friday last, Jan. 17th, have taken the advocates for the admission of women to the examinations of the English Colleges one step nearer their aim, but the whole question is still in considerable confusion. We need not go into the back history of the matter; it is sufficient to state that the present position is as follows. Petitions have been presented from the London School of Medicine for Women to both Colleges asking that women may be admitted to the examinations of the Colleges. The Council of the Royal College of Surgeons of England agreed to admit women to the examinations for the Membership only, the Fellowship being reserved for men; but the Council undertook before coming to a final decision to submit the matter to the Fellows and Members of the College, as was only right, seeing how drastic a change in constitution was contemplated. We presume that in the case of a distinct expression of opinion from the constituency the governing body of the College will alter its view, but pending the result of the plebiscite the Royal College of Surgeons of England is willing to give its Membership to women. The Comitia of the Royal College of Physicians of London, which is, of course, a far larger body and more representative of corporate views than the Council of the Royal College of Surgeons of England, has now made its reply to the petition of the London School of Medicine for Women. The Comitia has passed a resolution to admit women to all the examinations of its College, but the effect of this resolution is considerably minimised by the adoption of the rider of the registrar, Dr. E. Liveing, that it is not intended that any action should be taken under the resolution inconsistent with that agreement between the Royal College of Physicians of London and the Royal College of Surgeons of England by which the Licence of the former and the Membership of the latter are only granted conjointly. It would seem, then, that if the vote of the Fellows and Members of the Royal College of Surgeons of England should be against the admission of women to the examination for the Membership of that College women might still be prevented from being examined for the Licence of the Royal College of Physicians of London; they might, however, be able to sit for the Membership of that College. We conclude as we began—the whole question is in considerable confusion.

"RES MEDICA, RES PUBLICA."

THOSE of our readers who remember the interesting and suggestive address delivered at St. George's Hospital in October last by Dr. William Ewart will welcome its publication in pamphlet form by Messrs. Baillière, Tindall, and Cox. Dr. Ewart completely emancipated himself from timeworn first of October topics and addressed himself to a consideration of some of the most pressing of the economic evils against which the medical profession, as a whole, is called upon to contend. Of some of these evils and of the roots from which they spring he submitted a graphic description to his hearers, and he discussed in some detail the most serious of the causes which interfere with the due recognition and the due remuneration of thoroughly unsound one; what was good enough for our fathers is not good enough for us in matters of hygiene, seeing how much fuller is our knowledge of the importance of little things than was theirs, and in this instance apparently a Government department seeks to deprive its employees of a hygienic advantage which even their fathers enjoyed.

PLAGUE AT ACCRA.

THE following telegram from the Acting Governor of the Gold Coast was received at the Colonial Office on Jan. 15th: "Total number of deaths from plague up to midnight, 14th January, fifteen. Thirteen natives in Contagious Diseases Hospital and Isolation Camps, one death reported this morning. Garland (Deputy Principal Medical Officer) believes progress of plague effectively checked. Sufficient number of medical officers here. In order to get into closer touch with natives have authorised temporary employment of Papafio, retired medical officer, Bruce, native medical practitioner, also Fisch, German doctor of some scientific attainments. There are now six doctors available at Accra. Large number of dead rats has been observed, Accra; every endeavour has been made from the beginning to exterminate rodents." The Secretary of State for the Colonies has appointed Dr. W. J. R. Simpson, professor of hygiene at King's College, London, and lecturer in tropical hygiene at the London School of Tropical Medicine, to proceed to the Gold Coast to assist in combating the present outbreak of bubonic plague at Accra. He left for the Gold Coast by the steamship *Mendi* on Jan. 18th and was accompanied by Dr. J. A. Haran of the medical service of the East Africa Protectorate, who has been selected on account of his experience in dealing with plague in that dependency. Dr. Simpson's mission to Accra shows that the Government wishes to leave nothing undone that can possibly be of service to our Gold Coast Dependency but implies no want of confidence in the ability of the medical staff now on the spot. Dr. Simpson will probably also visit other towns in West Africa with a view to advising in regard to questions of sanitation. Since his departure two official telegrams have been received at the Colonial Office showing that on Jan. 20th six, and on Jan. 21st two, deaths occurred from bubonic plague. On the latter date the return shows 48 cases isolated.

UNCERTIFIED CAUSES OF DEATH IN 1907.

ALTHOUGH successive Governments have failed to take any action for giving effect to the recommendations made in the report issued by Sir Walter Foster's Committee in 1892 on the Certification of Causes of Death the number and proportion of uncertified deaths in England and Wales have since then constantly declined under the influence of the attention given to the subject in the reports of the Registrar-General and of the local medical officers of health. In the last issued annual report of the Registrar-General (1905) it was shown that the proportion of uncertified deaths steadily declined from 1·81 per cent. in 1900 to 1·62 in 1905; his quarterly returns for 1906 showed a further decline to 1·53, and during the first three quarters of 1907 the percentage of uncertified causes of death did not exceed 1·44. The quarterly and weekly returns for 1907, moreover, enable us to consider and to compare the varying proportions of uncertified deaths in the 76 large English towns dealt with in those returns during 1907. The mean percentage of uncertified deaths in these 76 towns was 1·1 in 1904 and in 1905, 1·0 in 1906, and further declined to 0·9 in 1907. The mean proportion of uncertified deaths has thus been considerably lower in these 76 towns than the mean rate in the whole of England and Wales in each of the last four years, and it is satisfactory to note that the proportions continue to decline in the large towns as well as in the whole of England and Wales. It is, however, still more important that attention should be called to the wide variations in the reduced proportions of uncertified deaths still prevailing among these 76 towns. During 1907 all the causes of deaths registered in Croydon, Tottenham, Southampton, Wigan, Hornsey, Devonport, Ipswich, and Great Yarmouth were duly certified, and all but one of the causes of death registered during the year were duly certified in West Ham, Brighton, Walthamstow, Plymouth, and Bournemouth. In London the proportion of uncertified deaths last year did not exceed, as we recently pointed out, 1 per 1000 deaths registered, whereas the proportion had been equal to 2 per 1000 in each of the three preceding years. In many other of the 76 towns, however, there is still a marked excess of uncertified deaths, showing a want of appreciation of the importance of the due certification of all causes of death either by a registered medical practitioner who has been in attendance during the last illness of the deceased or by a coroner after inquest. The proportion of uncertified deaths during last year was equal to 2·7 per cent. of the deaths registered in Liverpool and in Bootle, to 2·8 per cent. in Sunderland and in Burton-on-Trent, 2·9 in Preston, 3·3 in Birmingham, 3·5 in St. Helens, 4·4 in Gateshead, 4·5 in Warrington, and 5·1 in South Shields. It would be useful as well as interesting to have some explanation of the fact that while it has been found possible to secure the due certification of all causes of death in the eight above-mentioned towns, and of all but 1 per 1000 in very many other towns, the proportion of uncertified deaths last year should have exceeded 27 per 1000 in the towns referred to above, ranging up to 51 per 1000 in South Shields. It is beyond question that even under the present legislative arrangements due coöperation between sanitary authorities, medical officers of health, and coroners would undoubtedly reduce the number of uncertified deaths to an inconsiderable minimum.

"IONIC MEDICATION."

IN addition to the discovery of new methods of treatment in medicine and surgery it is interesting to note how modern scientific ideas bring about the revival of an old method which, probably for the want of a better knowledge, had been allowed to fall into disuse. An instance of this is the local introduction of drugs through the unbroken skin with the aid of the electric current. This is generally known as cataphoresis, and the method is nearly as old as our knowledge of the electrolytic process itself. At one time it was employed to a considerable extent both at home and abroad, but it was not until Professor Leduc of Nantes brought his encyclopædic knowledge of electrolysis to bear on the subject that it received a more scientific foundation and a fresh lease of life. In the electrolysis of a normal saline solution there is a migration of ions; the basic (sodium) ions travel from the anode to the cathode, while the acid (chlorine) ions move from the cathode to the anode. This process is not stopped by the intervention of animal membrane or skin. As being more in harmony with modern ideas the method is sometimes spoken of as "ionic medication." As our knowledge and experience increase there is every probability that this principle will be employed in a gradually increasing degree. It has been found very useful, for instance, in the stiffness following a severe sprain of the ankle-joint: a pad wet with a watery solution of iodine was placed over the part and covered with a metal plate connected to the positive pole. Cases of trigeminal and supra-orbital neuralgia have been relieved by the similar use of quinine or salicylic acid after all other methods had failed. Local anæsthesia can be produced with a solution of cocaine. Small and superficial rodent ulcers are easily cured by anyone who has had a little experience. Here a solution of zinc chloride is used and the zinc ions are which the patient craves. If so much water is taken that the stomach becomes distended the catheter forms a perfect safety valve through which the stomach can be emptied at once. Thus the most urgent symptom following the operation can be relieved with safety and what is evidently a want of nature supplied. With regard to food, Mr. Richardson considers nutrient enemata as a poor substitute for food absorbed by the proper organs. When the ulcer is closed in the ordinary manner the surgeon dare not feed the patient by the mouth because after the operation its functions, like those of any injured organ, are impaired and it can only partially digest food. Thus food, if given, would accumulate, ferment, and do great harm unless removed by a stomach-pump—a dangerous operation in the circumstances. Therefore nutrient enemata have to be relied upon. By making use of the ulcer as a gastrostomy opening Mr. Richardson claims that the danger of feeding by the stomach is removed and at the same time an amount of nourishment is given, which could not be given by the rectum. He feeds the patient by the mouth every four hours with beef-tea and milk. Thus the pleasure and stimulation arising from the act of swallowing are preserved. Before each feeding the stomach is washed out with a solution of bicarbonate of sodium, so that what remains of the previous meal is removed. Moreover, the patient is not disturbed as when enemata are given but, on the contrary, is afforded great comfort. The washing out with bicarbonate of sodium is so comforting that the patients often ask the nurse to repeat it. After four or five days, when the patient is seen to be on the road to recovery, the catheter is withdrawn. The opening closes immediately, no leakage takes place, and no hernia follows. Mr. Richardson's experience of this method is encouraging but not yet sufficient to furnish statistics as to its advantages.

AN ORGANIC SERUM FOR THE TREATMENT OF SYPHILIS.

THE official bulletin of the Society of Biology of Paris in its account of the proceedings of a meeting held on Dec. 21st, 1907, gives a paper by Professor Hallopeau, physician to the Hospital of St. Louis and a Member of the Academy of Medicine. The paper dealt with the results obtained in syphilitic patients under the care of Professor Hallopeau by the use of an organic serum prepared by Dr. Quéry who in a paper read before the society on March 9th last gave as his conclusion that the pathogenic agent of syphilis was a bacillus which reproduces itself by spores and of which the spirillum of Schaudinn is an involutionary form. Confirmatory evidence of the truth of this theory has since been obtained by Leuriaux and Geest, Bertarelli and Volpino, Benda, Krzyzstalowicz, and Siedlecki. The isolation of the bacillus in question has enabled Dr. Quéry to prepare an organic antisyphilitic serum which is prepared and used after the same method as the well-known antidiphtheritic serum. Professor Hallopeau mentioned that 20 cases had been treated with the serum and that a progressive improvement had been observed in every one of them. To use his own words: "The ameliorations observed should not be laid to the account of the normal evolution of the disease, for I have noted them as taking place from the very beginning of the secondary symptoms and they therefore indicate a definite action of the serum upon the evolution of the disease. As to whether the ameliorations will be lasting, my studies in the question are at present too recent to give a definite answer." Dr. Quéry in a note which he has sent to us allows that at present the word "cure" should not be employed with regard to the action of the serum upon syphilis, but he has had under his personal notice certain patients who were treated four years ago and in whom there has been no apparent relapse. Professor Hallopeau concludes his paper by saying that the serum should be used in association with atoxyl or mercury and iodide of potassium. There is no incompatibility between the treatments and it is necessary to make use of every available weapon against such a resourceful enemy as syphilis.

AN AUSTRIAN PROFESSOR'S REMINISCENCES.

Professor Moritz Benedikt of Vienna has published his reminiscences in a lengthy but interesting volume.[1] Born in 1835 in Eisenstadt in Odenburg, now known by its Hungarian name of Kis-Márton, his childhood was passed under the feudal and autocratic *régime* which then ruled in Austria, his boyhood during the stirring times of the revolution, while during his student career at Vienna the university of that city owned some of the greatest names in its history. A man of wide interests, not confined to purely professional subjects but embracing literature, art, politics, and music, he has been also through two military campaigns, those of 1859 and 1866, and has travelled widely in most of the European countries, and having in the course of his long and active life met many notable personalities on more or less intimate terms he has a great many interesting reminiscences to record. His descriptions of his early school days and of his later studies at the gymnasium or high school afford noteworthy pictures of the educational methods of the first half of the nineteenth century in Austria. During the time when he was at the gymnasium at Vienna, between 1845 and 1853, the revolution occurred, and he has various anecdotes of those troubled times to relate. Apparently of studious habits from early in his life, he studied languages assiduously and acquired a considerable knowledge of the literature of Greece, England, and France, as well as of the writings of German poets and historians. Of the Greeks he liked best Homer, Sophocles, Euripides, and Demosthenes. In English he read widely. He states that Shakespeare was his poetical and psychological bible, and in his anxiety to read his works in the original he bought a copy of "Macbeth" after taking a few English lessons and looked out over 300 words in the dictionary, writing their meaning beside the text in shorthand. By reading this play through several times he so increased his vocabulary that he was able to read the other plays without any conspicuous difficulty. He naturally had a great affection for Goethe and Schiller and writes most appreciatively of Grillparzer and Kleist. Heine he regards as the greatest lyrist since the Psalmist. A most pleasing section of Professor Benedikt's book is that devoted to his years as a student at the University of Vienna. His brief character sketches of some of the distinguished professors under whom he studied serve to bring before us very clearly some of the men who helped to give Vienna its great reputation as a medical centre. Among these we may mention Hyrtl, Brücke, Rokitansky, Skoda, Arlt, and Oppolzer. He also came into relation with Semmelweis, whose tragic story he refers to in feeling terms, and was intimate with Hebra and Karl Ludwig. Hyrtl possessed remarkable abilities as a lecturer and in the preparation of anatomical specimens. Benedikt describes him as an artist in all that he undertook. He was very popular among his students but not among his professorial colleagues. Brücke is represented as a man of somewhat cynical, unattractive personality whose lectures were often beyond the scope of his audience. In spite of these characteristics and of his severity at examinations, he seems to have acquired the respect of his students. Of Rokitansky, Benedikt writes with enthusiasm and extols his pioneer work in pathology. He was not a great lecturer but was a most thorough and illuminating worker.

---

thoroughly unsound one; what was good enough for our fathers is not good enough for us in matters of hygiene, seeing how much fuller is our knowledge of the importance of little things than was theirs, and in this instance apparently a Government department seeks to deprive its employees of a hygienic advantage which even their fathers enjoyed.

PLAGUE AT ACCRA.

THE following telegram from the Acting Governor of the Gold Coast was received at the Colonial Office on Jan. 15th: "Total number of deaths from plague up to midnight, 14th January, fifteen. Thirteen natives in Contagious Diseases Hospital and Isolation Camps, one death reported this morning. Garland (Deputy Principal Medical Officer) believes progress of plague effectively checked. Sufficient number of medical officers here. In order to get into closer touch with natives have authorised temporary employment of Papafio, retired medical officer, Bruce, native medical practitioner, also Fisch, German doctor of some scientific attainments. There are now six doctors available at Accra. Large number of dead rats has been observed, Accra; every endeavour has been made from the beginning to exterminate rodents." The Secretary of State for the Colonies has appointed Dr. W. J. R. Simpson, professor of hygiene at King's College, London, and lecturer in tropical hygiene at the London School of Tropical Medicine, to proceed to the Gold Coast to assist in combating the present outbreak of bubonic plague at Accra. He left for the Gold Coast by the steamship *Mendi* on Jan. 18th and was accompanied by Dr. J. A. Haran of the medical service of the East Africa Protectorate, who has been selected on account of his experience in dealing with plague in that dependency. Dr. Simpson's mission to Accra shows that the Government wishes to leave nothing undone that can possibly be of service to our Gold Coast Dependency but implies no want of confidence in the ability of the medical staff now on the spot. Dr. Simpson will probably also visit other towns in West Africa with a view to advising in regard to questions of sanitation. Since his departure two official telegrams have been received at the Colonial Office showing that on Jan. 20th six, and on Jan. 21st two, deaths occurred from bubonic plague. On the latter date the return shows 48 cases isolated.

UNCERTIFIED CAUSES OF DEATH IN 1907.

ALTHOUGH successive Governments have failed to take any action for giving effect to the recommendations made in the report issued by Sir Walter Foster's Committee in 1892 on the Certification of Causes of Death the number and proportion of uncertified deaths in England and Wales have since then constantly declined under the influence of the attention given to the subject in the reports of the Registrar-General and of the local medical officers of health. In the last issued annual report of the Registrar-General (1905) it was shown that the proportion of uncertified deaths steadily declined from 1·81 per cent. in 1900 to 1·62 in 1905; his quarterly returns for 1906 showed a further decline to 1·53, and during the first three quarters of 1907 the percentage of uncertified causes of death did not exceed 1·44. The quarterly and weekly returns for 1907, moreover, enable us to consider and to compare the varying proportions of uncertified deaths in the 76 large English towns dealt with in those returns during 1907. The mean percentage of uncertified deaths in these 76 towns was 1·1 in 1904 and in 1905, 1·0 in 1906, and further declined to 0·9 in 1907. The mean proportion of uncertified deaths has thus been considerably lower in these 76 towns than the mean rate in the whole of England and Wales in each of the last four years, and it is satisfactory to note that the proportions continue to decline in the large towns as well as in the whole of England and Wales. It is, however, still more important that attention should be called to the wide variations in the reduced proportions of uncertified deaths still prevailing among these 76 towns. During 1907 all the causes of deaths registered in Croydon, Tottenham, Southampton, Wigan, Hornsey, Devonport, Ipswich, and Great Yarmouth were duly certified, and all but one of the causes of death registered during the year were duly certified in West Ham, Brighton, Walthamstow, Plymouth, and Bournemouth. In London the proportion of uncertified deaths last year did not exceed, as we recently pointed out, 1 per 1000 deaths registered, whereas the proportion had been equal to 2 per 1000 in each of the three preceding years. In many other of the 76 towns, however, there is still a marked excess of uncertified deaths, showing a want of appreciation of the importance of the due certification of all causes of death either by a registered medical practitioner who has been in attendance during the last illness of the deceased or by a coroner after inquest. The proportion of uncertified deaths during last year was equal to 2·7 per cent. of the deaths registered in Liverpool and in Bootle, to 2·8 per cent. in Sunderland and in Burton-on-Trent, 2·9 in Preston, 3·3 in Birmingham, 3·5 in St. Helens, 4·4 in Gateshead, 4·5 in Warrington, and 5·1 in South Shields. It would be useful as well as interesting to have some explanation of the fact that while it has been found possible to secure the due certification of all causes of death in the eight above-mentioned towns, and of all but 1 per 1000 in very many other towns, the proportion of uncertified deaths last year should have exceeded 27 per 1000 in the towns referred to above, ranging up to 51 per 1000 in South Shields. It is beyond question that even under the present legislative arrangements due coöperation between sanitary authorities, medical officers of health, and coroners would undoubtedly reduce the number of uncertified deaths to an inconsiderable minimum.

"IONIC MEDICATION."

IN addition to the discovery of new methods of treatment in medicine and surgery it is interesting to note how modern scientific ideas bring about the revival of an old method which, probably for the want of a better knowledge, had been allowed to fall into disuse. An instance of this is the local introduction of drugs through the unbroken skin with the aid of the electric current. This is generally known as cataphoresis, and the method is nearly as old as our knowledge of the electrolytic process itself. At one time it was employed to a considerable extent both at home and abroad, but it was not until Professor Leduc of Nantes brought his encyclopædic knowledge of electrolysis to bear on the subject that it received a more scientific foundation and a fresh lease of life. In the electrolysis of a normal saline solution there is a migration of ions; the basic (sodium) ions travel from the anode to the cathode, while the acid (chlorine) ions move from the cathode to the anode. This process is not stopped by the intervention of animal membrane or skin. As being more in harmony with modern ideas the method is sometimes spoken of as "ionic medication." As our knowledge and experience increase there is every probability that this principle will be employed in a gradually increasing degree. It has been found very useful, for instance, in the stiffness following a severe sprain of the ankle-joint: a pad wet with a watery solution of iodine was placed over the part and covered with a metal plate connected to the positive pole. Cases of trigeminal and supra-orbital neuralgia have been relieved by the similar use of quinine or salicylic acid after all other methods had failed. Local anæsthesia can be produced with a solution of cocaine. Small and superficial rodent ulcers are easily cured by anyone who has had a little experience. Here a solution of zinc chloride is used and the zinc ions are which the patient craves. If so much water is taken that the stomach becomes distended the catheter forms a perfect safety valve through which the stomach can be emptied at once. Thus the most urgent symptom following the operation can be relieved with safety and what is evidently a want of nature supplied. With regard to food, Mr. Richardson considers nutrient enemata as a poor substitute for food absorbed by the proper organs. When the ulcer is closed in the ordinary manner the surgeon dare not feed the patient by the mouth because after the operation its functions, like those of any injured organ, are impaired and it can only partially digest food. Thus food, if given, would accumulate, ferment, and do great harm unless removed by a stomach-pump—a dangerous operation in the circumstances. Therefore nutrient enemata have to be relied upon. By making use of the ulcer as a gastrostomy opening Mr. Richardson claims that the danger of feeding by the stomach is removed and at the same time an amount of nourishment is given, which could not be given by the rectum. He feeds the patient by the mouth every four hours with beef-tea and milk. Thus the pleasure and stimulation arising from the act of swallowing are preserved. Before each feeding the stomach is washed out with a solution of bicarbonate of sodium, so that what remains of the previous meal is removed. Moreover, the patient is not disturbed as when enemata are given but, on the contrary, is afforded great comfort. The washing out with bicarbonate of sodium is so comforting that the patients often ask the nurse to repeat it. After four or five days, when the patient is seen to be on the road to recovery, the catheter is withdrawn. The opening closes immediately, no leakage takes place, and no hernia follows. Mr. Richardson's experience of this method is encouraging but not yet sufficient to furnish statistics as to its advantages.

AN ORGANIC SERUM FOR THE TREATMENT OF SYPHILIS.

THE official bulletin of the Society of Biology of Paris in its account of the proceedings of a meeting held on Dec. 21st, 1907, gives a paper by Professor Hallopeau, physician to the Hospital of St. Louis and a Member of the Academy of Medicine. The paper dealt with the results obtained in syphilitic patients under the care of Professor Hallopeau by the use of an organic serum prepared by Dr. Quéry who in a paper read before the society on March 9th last gave as his conclusion that the pathogenic agent of syphilis was a bacillus which reproduces itself by spores and of which the spirillum of Schaudinn is an involutionary form. Confirmatory evidence of the truth of this theory has since been obtained by Leuriaux and Geest, Bertarelli and Volpino, Benda, Krzyzstalowicz, and Siedlecki. The isolation of the bacillus in question has enabled Dr. Quéry to prepare an organic antisyphilitic serum which is prepared and used after the same method as the well-known antidiphtheritic serum. Professor Hallopeau mentioned that 20 cases had been treated with the serum and that a progressive improvement had been observed in every one of them. To use his own words: "The ameliorations observed should not be laid to the account of the normal evolution of the disease, for I have noted them as taking place from the very beginning of the secondary symptoms and they therefore indicate a definite action of the serum upon the evolution of the disease. As to whether the ameliorations will be lasting, my studies in the question are at present too recent to give a definite answer." Dr. Quéry in a note which he has sent to us allows that at present the word "cure" should not be employed with regard to the action of the serum upon syphilis, but he has had under his personal notice certain patients who were treated four years ago and in whom there has been no apparent relapse. Professor Hallopeau concludes his paper by saying that the serum should be used in association with atoxyl or mercury and iodide of potassium. There is no incompatibility between the treatments and it is necessary to make use of every available weapon against such a resourceful enemy as syphilis.

AN AUSTRIAN PROFESSOR'S REMINISCENCES.

Professor Moritz Benedikt of Vienna has published his reminiscences in a lengthy but interesting volume.[1] Born in 1835 in Eisenstadt in Odenburg, now known by its Hungarian name of Kis-Márton, his childhood was passed under the feudal and autocratic *régime* which then ruled in Austria, his boyhood during the stirring times of the revolution, while during his student career at Vienna the university of that city owned some of the greatest names in its history. A man of wide interests, not confined to purely professional subjects but embracing literature, art, politics, and music, he has been also through two military campaigns, those of 1859 and 1866, and has travelled widely in most of the European countries, and having in the course of his long and active life met many notable personalities on more or less intimate terms he has a great many interesting reminiscences to record. His descriptions of his early school days and of his later studies at the gymnasium or high school afford noteworthy pictures of the educational methods of the first half of the nineteenth century in Austria. During the time when he was at the gymnasium at Vienna, between 1845 and 1853, the revolution occurred, and he has various anecdotes of those troubled times to relate. Apparently of studious habits from early in his life, he studied languages assiduously and acquired a considerable knowledge of the literature of Greece, England, and France, as well as of the writings of German poets and historians. Of the Greeks he liked best Homer, Sophocles, Euripides, and Demosthenes. In English he read widely. He states that Shakespeare was his poetical and psychological bible, and in his anxiety to read his works in the original he bought a copy of "Macbeth" after taking a few English lessons and looked out over 300 words in the dictionary, writing their meaning beside the text in shorthand. By reading this play through several times he so increased his vocabulary that he was able to read the other plays without any conspicuous difficulty. He naturally had a great affection for Goethe and Schiller and writes most appreciatively of Grillparzer and Kleist. Heine he regards as the greatest lyrist since the Psalmist. A most pleasing section of Professor Benedikt's book is that devoted to his years as a student at the University of Vienna. His brief character sketches of some of the distinguished professors under whom he studied serve to bring before us very clearly some of the men who helped to give Vienna its great reputation as a medical centre. Among these we may mention Hyrtl, Brücke, Rokitansky, Skoda, Arlt, and Oppolzer. He also came into relation with Semmelweis, whose tragic story he refers to in feeling terms, and was intimate with Hebra and Karl Ludwig. Hyrtl possessed remarkable abilities as a lecturer and in the preparation of anatomical specimens. Benedikt describes him as an artist in all that he undertook. He was very popular among his students but not among his professorial colleagues. Brücke is represented as a man of somewhat cynical, unattractive personality whose lectures were often beyond the scope of his audience. In spite of these characteristics and of his severity at examinations, he seems to have acquired the respect of his students. Of Rokitansky, Benedikt writes with enthusiasm and extols his pioneer work in pathology. He was not a great lecturer but was a most thorough and illuminating worker.

ANNUAL REPORT FOR 1906 OF THE MEDICAL OFFICER OF HEALTH OF THE ADMINISTRATIVE COUNTY OF LONDON.

I.

Sir Shirley F. Murphy's fifteenth annual report on the health of the metropolis has recently been published by order of the London County Council. The volume occupies, with appendices, 180 folio pages of closely printed matter and is illustrated throughout with a series of appropriate diagrams. Whilst closely following, in its general features, the lines of its predecessors the present report contains a large amount of important matter which now appears for the first time. To this additional matter more especially we propose to refer in detail. Nevertheless, as this report is written primarily for the benefit of Londoners, we shall endeavour, as far as space permits, to notice any serious deviations from the normal records of mortality in the metropolis, relating as they do to a population closely approaching 5,000,000 in number.

The ordinary statistics of marriages, births, and deaths in the metropolis have already been published in the annual summary of the Registrar-General. It is, however, worthy of more than passing notice that the mortality of London both in 1906 and in the year immediately preceding was the lowest hitherto recorded. It was only 15·1 in each 1000 persons living and was below the average rate in the closing decade of the nineteenth century by more than 20 per cent. The London death-rate in 1906 tallies closely with that of England and Wales, the difference in the rates amounting to no more than a few tenths of a unit per 1000. It is common knowledge that the mortality of dwellers in the several districts of the metropolis varies enormously. By calculating the comparative mortality figure for each of the 29 metropolitan boroughs, which now correspond to the administrative sanitary areas, the county medical officer of health gives exact numerical expression to these variations. From a table in the report we see that in the quinquennial period ending with 1905, 11 of the metropolitan boroughs had a mortality in excess and 18 a mortality in defect of the average for the administrative county as a whole. The table further shows that in 1906 the mortality in the poor and populous district of Finsbury was at least double of that in the more highly favoured and less populous district of Hampstead. Carrying still further his analysis, Sir Shirley Murphy tells us that among the 21,000 tenants of the dwellings for the working classes recently provided by the County Council for the accommodation of persons displaced by the removal of house property for street or sanitary improvements, the rate of mortality did not exceed 13·7 per 1000, a rate which may be considered a low one for even the healthy districts of the country, and which is less by 1·4 per 1000 than the present average rate for the metropolis.

In the year 1906 London mortality from the principal epidemic diseases (except diarrhœa) was below the average for the preceding decennium. Small-pox was notified in only 31 cases, all of which recovered. Of the cases reported, nine occurred in Hackney, six each in Bethnal Green and Camberwell, and smaller numbers in other metropolitan boroughs. During the year the services of Mr. W. McC. Wanklyn, of the County Council's Public Health Department, were required to assist in the diagnosis of 35 cases of suspected small-pox. These included a group of four patients and another group of three patients, all of whom were found to be suffering from genuine small-pox; a group of five patients suffering from chicken-pox, and another group of five cases affected not with small-pox or chicken-pox but with contagious skin diseases.

Among the common infectious diseases of children neither measles nor whooping-cough is included in the schedule of the London Notification Act. Nevertheless, these diseases give considerable trouble to sanitary as well as education authorities by reason of the interference which they cause with the regularity of school attendance. The relation of overcrowding to the prevalence of measles is well shown in the present report, from which we learn that the mortality from this disease is more than twice as great in districts where over 27½ per cent. of the dwellings are overcrowded as it is in districts where the overcrowding does not exceed 7½ per cent. The question of the possible reduction in fatality that might be attained by the better nursing at home of cases of measles is discussed by the county medical officer as well as by certain of his colleagues. Sir Shirley Murphy refers with approval to the good services rendered in Woolwich by the district nursing institution there, an institution that would probably be instrumental in saving many of the lives which in present circumstances are sacrificed to measles if only the sanitary authorities possessed, and utilised, the power to contribute to the expenses of the association so as to enable it to employ a sufficient staff to cope with local requirements. The county medical officer also discusses the question of school closure as an expedient for dealing with excessive incidence of measles among children of tender age; but although in the year 1906 not fewer than 52 classrooms and 15 "departments" were closed on account of the prevalence of measles, this expedient does not appear to have produced the results which might have been hoped for; this is attributed to the fact that "there is no satisfactory system by which a teacher becomes aware of the cause of absence of a pupil." There appears to be some indication that parents nowadays regard measles as a more serious malady than was formerly the case and that as a consequence a larger proportion of the cases, in certain districts at any rate, come under medical care.

In the behaviour of scarlet fever during 1906 there is little abnormal to notice. Both the case-rate and the death-rate of the administrative county corresponded nearly to the average, although, as usual, the incidence of attacks from scarlet fever varied widely in the several metropolitan districts. Almost the same statement may be made concerning diphtheria, except that the prevalence, as well as the fatality, of this disease showed a greater defect from the average than was observed in the case of scarlet fever. But with regard to diphtheria Sir Shirley Murphy gives an interesting account of the occurrence of outbreaks among school children, in many of the cases the Klebs-Löffler bacillus being detected. This account, which will be read with interest by all medical men engaged in practical sanitation, is too long for reproduction here and scarcely admits of condensation.

As regards the bacteriological examination of "contacts" with cases of diphtheria very interesting particulars are given in the present report. In certain districts the local medical officers of health have been able to secure that no "contact" should be allowed to return to school after illness from diphtheria except after bacteriological examination of the fauces. In this connexion the London County Council has adopted an important report and resolution submitted to it by its Education Committee, from which the following is an extract:—

> Our attention has been drawn to the difficulties which have arisen in districts where diphtheria has been prevalent, consequent upon children who have been excluded from school being certified as free from disease by medical practitioners. With the view, therefore, to dealing more thoroughly with the disease, the various medical officers of health were asked to adopt the temporary arrangements being carried out in Greenwich in the event of there being an outbreak of diphtheria in their respective districts. These arrangements involve that any children excluded from school on account of diphtheria or sore-throat during the prevalence of the disease should not be re-admitted without a certificate from the medical officer of health that they are free from infection. ...... We are of opinion that it would greatly strengthen the hands of the various medical officers and do much to reduce the present risks of infection if authority were given for the refusal, during the presence of diphtheria in any district, of the readmission of children excluded from school as suffering from diphtheria or sore-throat until they have obtained a medical certificate of freedom from infection based on a bacteriological examination. We are informed that such certificates can be given, either by general practitioners or by medical officers of health, and wou'd be free from the dangerous errors of medical certificates given merely on the inspection of children.

The Education Committee, after carefully debating the subject, passed the following most important resolution, which, as we said before, was adopted by the County Council:—

> We recommend that the Education Committee be authorised to refuse, during the presence of diphtheria in any district, readmission to school of children excluded on account of diphtheria or sore-throat until such children shall have obtained a medical certificate of freedom from infection, based on a bacteriological examination.

In our opinion it is difficult to over-estimate the value of this far-seeing resolve on the part of the London County Council as the supreme educational authority. Probably no step could have been taken that would be more likely than this to check the spread of infection in elementary schools—that credit of drawing attention to these cases and their importance as centres of infection. He states that 93 per cent. of persons convalescent from enteric fever do not discharge typhoid bacilli in the stools after the fifteenth day from the time when the temperature has fallen to normal, and further that of the remainder many soon cease to harbour the bacilli, leaving about 3 per cent. of carriers. Klinger after examining the stools of a large number of cases of persons who had suffered from enteric fever found that only 1·7 per cent. became chronic "typhoid carriers," a smaller percentage than that found by Kayser but the result of a more extended examination. From the intermittent character of the discharge of bacilli by these "typhoid carriers" in the fæces it is suggested that it is in the gall-bladder that the organisms live and multiply. It is well known that bile is a good culture medium for them, that they are not infrequently found in gall-stones, and Dehler has treated cases of "typhoid carriers" by draining the gall-bladder, after which operation the bacilli disappeared in the course of a few months. That the bacilli may also remain in other situations for long periods is proved by the case recorded by Mr. L. S. Dudgeon and Dr. R. E. G. Gray[2] in which typhoid bacilli were recovered from bone lesions three and a half years after an attack of enteric fever. In an annotation[3] commenting upon the case we pointed out the necessity for dealing effectively with all the discharges from patients suffering from that disease. The question of the recognition of these cases is obviously one of importance and Kayser suggests that the stools and urine of convalescent cases of enteric fever should be examined at intervals of a fortnight and three weeks after the temperature has fallen, and if these examinations prove negative a third trial should be made after several months. If any one of the three gives a positive result the examination should be repeated at weekly intervals until three consecutive negative results are obtained. He also recommends that known "typhoid carriers" should be kept under bacteriological supervision. Even by such drastic methods it is not possible to be certain of discovering all the cases, and it is obvious that if such a rigorous control is to be kept over the patients who have suffered from enteric fever it is quite beyond the province of the ordinary practitioner and must come under the control of the health authorities. An equally difficult problem is offered in the treatment of these cases. Being apparently in perfect health they are not likely to submit to treatment by antiseptics or to the more drastic surgical procedure adopted by Dehler, even if these methods are found to be effective. At present all that can be done is to discover them and to prevent them from becoming sources of infection, as the instance above quoted shows.

THE TRAFFIC IN OLD HORSES.

THERE are certain offences against humanity and civilisation to which we are obliged periodically to refer and the brutalities incidental to the shipment of old and worn-out horses have been brought before our readers on many previous occasions. The latest case of this kind of which we have knowledge occupied the attention of Mr. Biron at Old-street police court on Jan. 16th when a man named Spratt *alias* Sharpe was charged with cruelty to a horse by leading it in a lame condition through the streets under the Cruelty to Animals Act. The horse was, as usual, destined to be shipped abroad. We pointed out in THE LANCET of April 11th, 1903, p. 1045, that this is the only Act which covers the particular offence, for the Order of the Board of Agriculture issued at the beginning of 1899 to deal with the matter only stated that it should be unlawful to convey from any port in the British Isles to any place outside them "any horse which, owing to age, infirmity, illness, fatigue, or any other reason, cannot be so conveyed without cruelty during the intended passage and upon landing." In the present case it was proved that the man had been twice convicted of cruelty in the same connexion. Mr. Biron sentenced him to three months' hard labour after making some remarks such as we have frequently expressed in those columns.[1] He said that he could not understand why the people behind the men employed to take such poor things through the street were not proceeded against. The very shippers and people on the boats must know that they had been exposed to great cruelty to make them travel. The trade was shocking, disgusting, and horrible. He could only make an example of the prisoner as the police said that there were difficulties in the way of reaching the men who hired him, though he could not understand why. We cannot understand why, either. Surely it is desirable that legislation should render the export of old horses for foreign food a criminal offence and we urge on the present Government the expediency of bringing in a small Bill, which would probably become law with little controversy, to abolish entirely this traffic.

THE FOURTH INTERNATIONAL CONGRESS ON ELECTROLOGY AND RADIOLOGY.

THE Fourth International Congress on Electrology and Radiology will be held at Amsterdam from Sept. 1st to 5th, 1908. The results of the three former Congresses—at Paris in 1900, at Berlin in 1903, and at Milan in 1905—having proved their utility and importance, the Fourth Congress will be organised on the same lines. The programme will comprise electrophysiology and electropathology, electrodiagnostics and electrotherapeutics, diagnostics and therapeutics of roentgen rays, the study of diverse radiations, and medical electrotechnics. In conjunction with the Congress an exhibition will be arranged of new or modified apparatus used in clinical and laboratorial work and also a collection of important radiographs. The Congress and the exhibition will be held in the University of Amsterdam, the executive committee being Professor Dr. J. K. A. Wertheim Salomonson, president, and Dr. J. G. Gohl and Dr. F. S. Meijers general secretaries and treasurers. Further information can be obtained from the secretaries by addressing them at Vondelstraat 53, Amsterdam.

A CURIOUS ECONOMY.

THE *Daily Telegraph* of Jan. 10th prints a curious story of Post Office economy contributed by a correspondent. The General Post Office, it says, has ceased to supply "dampers" to the clerks for sorting papers quickly, the official reason being that "dampers cost money, and we already pay for the use of fingers." That is well enough but the department does not pay for the use of tongues for other purposes than talking. The clerks are apparently alive to this and have, according to our contemporary's informant, improvised dampers by doubling several sheets of blotting-paper together to avoid the necessity of licking their fingers for the work, with the result that the makeshift is likely to cost more than the proper appliance. If this story be correct we can only hope that the authorities will speedily restore the old dampers and will do everything in their power to discourage the habit of finger-licking. Not only is it dirty in itself but the fact that the same forms may be handled by the licked fingers of different men at a short interval makes it a possible source of infection. Tuberculosis is far from uncommon in the Post Office service and it is not unlikely that the sick-pay given to one man whose lungs became thus infected would go a long way towards the provision of dampers throughout the department. The principle, too, is a

Subject to the economical law of supply and demand the medical profession, after passing through a painful period of more or less prolonged malaise, will most likely cease to be overcrowded.

But it is a more serious danger which threatens us, a danger against which we ought to take immediate steps: it is the descent of the physician into the ranks of paid servants and (State) functionaries. These terms are synonymous; a physician becomes a paid servant when he enters the employment of a master or of any society which appoints him with the object of using his services at their discretion. If the society which employs the physician is the State, the department, or the commune, he becomes a functionary.

This condition of affairs tends to spread because many young medical men, like most young men of the middle-class, are wanting in initiative, in activity, and in energy, and prefer a badly paid appointment to the more laborious and more difficult struggle which building up a private practice entails. Besides, all those who in any way are at the head of any group of men, as owners of factories, company directors, presidents of mutual aid societies, clergy, mayors, administrators, or politicians, seek to increase medical appointments. They hope to succeed in making the practitioner a servant by having him in their pay, and the more important his social rôle becomes the more they believe it is to their interest to enslave him.

Up to the present the State appointments assigned to medical men have been services of public utility in which medical coöperation appeared much more appreciated than free and independent action. These appointments, connected with poor relief, with control, with sanitation, with various expert examinations (in which the medical man, poorly paid, looked only to his conscience), were considered legitimate and caused prejudice to no other medical practitioner. But gradually certain of these appointments will be turned into veritable administrative offices, the medical men will attend, under orders and at a reduced price, the patients on their lists. Political and religious struggles will intervene and the medical man will be obliged to become an electoral agent and to espouse the cause of the political tyrant of his district. Coöperation—that useful and fruitful work which properly organised and confined to its beneficent rôle could assist greatly in solving appropriately the difficulties of the social problem—has too often given the saddening spectacle of a brilliantly decorated theatre on the stage of which a medical man appears in some badly dissimulated political farce. Relegated to a servile condition the medical man can no longer fulfil the important rôle which it seems the evolution of science must intrust to him. For such a high mission moral qualities are necessary, which complete independence can alone assure. But the undignified competition for these medical appointments increases daily. Those who employ us find a decided advantage in this unbridled competition and seek, without any scruple, to benefit from it. This enslaving of the medical man—this degradation of a salary substituted for an honorarium—gradually brings about in the medical profession the formation of a proletariat, a proletariat so much the more dangerous as it is an intellectual proletariat.

Before these dangers the medical profession has quite naturally reacted, and as a means of defence developed the *entente syndicale*. Practitioners have little by little found out that isolated they could no longer resist the demands of powerful societies. They formed themselves into groups and in order to show more clearly the defensive object of those groups they gave them the form of syndicates. The movement has taken 25 years for its production, but if the beginnings of the medical syndicate have been difficult and slow we can state with some pride that their progress has been constant and that their power of action has been able, usefully and vigorously to make itself manifest of late years, that at last we are in a position to hope that they will be capable of facing the difficulties of the present situation.

During many years the medical syndicates resisted the abuses of which practitioners complained in their localities, but only in an isolated manner and without coördinating their efforts. Little by little, however, in the course of action by the syndicates a principle was evolved which, if successfully applied, will deal a fatal blow to the salaried and functionary practitioner. This is the free choice of a medical man by the patient.

The principle of the free choice of a medical man by the patient, which we have called 'the liberty of confidence,' is not one of those theoretical ideas started for the occasion and issue of a dreamer's brain, as Minerva came forth fully armed from the head of Jupiter. It is a practical conception which the syndicates have only adopted after proving the possibility of its application. It began in the organisations for gratuitous medical assistance before the law of 1893. Since the application of this law a very liberal organisation has been established in certain districts allowing the pauper to have recourse to the medical practitioner of his choice. This organisation, which was started in the departments of Landes and of the Vosges, has removed the greatest objections to the 'organisation of medical assistance' (for the poor) and has now been adopted by two-thirds of France. It is needless to say that all the medical syndicates persistently demand its application. We will not enter into the working details of the Vosgian system, which requires payment by visit and by kilometre travelled and the establishment of control commissions for the prevention of abuses which are always possible.

The legislature, in making employers liable for the cost of medical attendance on injured workmen, had to settle the conditions under which this attendance should be given. After a very lively struggle against the insurance companies who wished at any cost to monopolise the attendance required by the victims of accidents at work; after having had to defend themselves against a number of their colleagues who, even in the councils of the medical syndicates, defended this monopoly, thus sacrificing the general interest for their personal advantage, the medical syndicates succeeded in having 'the liberty of the choice of a medical man' recognised by the law. They did better, thanks to the energy, devotion, and inflexible tenacity of Dr. Diverneresse who devoted himself entirely to this task; they succeeded in having inserted in Article 30 of the law penal provisions against any person who offered obstruction to the right of the injured person to choose his medical man. The legislature, at the request of the medical syndicates, guided by Dr. Diverneresse, even added to the law a regulation of medical etiquette by stating in Paragraph 5 of Article 4 that the medical man employed to obtain information for the employer or for the insurance company as to the condition of the injured workman could only do so 'in presence of the medical man in attendance who should have notice by letter two days beforehand.'

The promulgation of this law of April 9th, 1898 (amended March 22nd, 1902, and March 31st, 1905), was a victory for the medical profession the consequence of which may be considerable, and which in any case clearly indicates the way in which it ought to move in order to insure independence and dignity for the practitioner, while preventing his descent into the ranks of salaried officials and functionaries. It is thus that the liberty of confidence becomes the corner-stone of medical independence. Is there a more solid base than this to serve as a rallying point for the work of the medical syndicates? Have not revolutions been started for much less worthy liberties?

The liberty of confiding his defects and his miseries, his health and that of his family to a medical man whom he knows, whom he esteems, in whom he has faith: is this not the most sacred liberty and that which ought to be the most inviolable? And is it not violated daily, this individual liberty, in that which is the most delicate, the most intimate, by public and private administrations and by mutual aid societies, which impose upon the patient treatment by an official or salaried medical man? Always received with apprehension and distrust, this medical man will have to exert prodigious devotion, mildness, and tact in order to gain the confidence of patients who are forced to receive him. And if, in consequence of a death, a family suspects this medical man of inability or of negligence what an intolerable position it would be for him if his duties called him again to those who believed that they had been victimised by him. He would find dark and hostile countenances and anxious glances. He would feel that the patient had no confidence in him, that he only half harkened to his advice, that in these circumstances the best treatment could not be fruitful, and the least complication, the least incident would be cast up to him as a crime. Intimately convinced that without the confidence of the patient the task of the medical man is incompatible with his dignity the associated medical men have vigorously proclaimed respect for it.

When all the medical men of a town or district are united they should be able to take up seriously the study of questions of hygiene and of prophylaxis. Solidly organised driven into the surface of the ulcer which has been previously cleaned. If the ulcer is small and the application is carefully and thoroughly done, once only will be found sufficient to cause its disappearance. It is probable that it will be applied successfully in other conditions such as ringworm, and lupus vulgaris would appear to be one likely to be influenced favourably by the local introduction of some ion prejudicial to the life of the bacillus. There should also be a large field open to investigation in regard to its use in gouty and rheumatic deposits. Theoretically an objection to this method is that the substance introduced would be washed away by the circulation *before it* had penetrated very deeply. While this is no doubt true to a certain extent it is none the less true that the process at times enables a more pronounced local action to be produced of, say, iodine than is possible by the administration of iodides in the usual way.

ROYAL COLLEGE OF SURGEONS OF ENGLAND: THE LECTURE ARRANGEMENTS FOR 1908.

THE annual course of lectures to be delivered at the Royal College of Surgeons of England will commence on Feb. 10th and will be continued on each Monday, Wednesday, and Friday until March 20th. The lecture hour will be 5 P.M. each day. Erasmus Wilson lectures: Mr. S. G. Shattock will deliver one lecture on Ovarian Teratomata on Feb. 10th; Dr. J. W. H. Eyre, one lecture on the Importance (surgically) of the Pyogenetic Activities of Diplococcus Pneumoniæ on Feb. 12th; and Mr. L. S. Dudgeon, one lecture on Infection of the Urinary Tract due to Bacillus Coli, on Feb. 14th. Hunterian *lectures*: Dr. Victor Bonney will deliver three lectures on a Study of the Connective Tissues in Carcinoma and in Certain Pathological Conditions preceding its Onset, on Feb. 17th, 19th, and 21st; Mr. Donald J. Armour, three lectures on the Surgery of the Spinal Cord and its Membranes, on Feb. 24th, 26th, and 28th; Dr. F. C. Shrubsall, three lectures on the Physical Anthropology of the Pigmy and Negro Races of Africa, on March 2nd, 4th, and 6th; Mr. A. Ralph Thompson, two lectures on the Anatomy of the Long Bones relating to certain Fractures, on March 9th and 11th; and Mr. W. S. Handley, one lecture on the Natural Cure of Cancer, on March 13th. Arris and Gale lectures: Dr. F. A. Bainbridge will deliver one lecture on the Pathology of Acid Intoxication, on March 16th, and Mr. M. Greenwood, jun., two lectures on the Physiological and Pathological Effects which Follow Exposure to Compressed Air on March 18th and 20th.

THE LAHORE MEDICAL COLLEGE.

THERE is a quaint old saying or proverb to the effect that "Soft words butter no parsnips." Doubtless the apothegm is an onomatopoetic corruption of another in a different language, couched in more dignified terms and possibly possessing a different meaning, but be this as it may the modern meaning was well exemplified at the annual prize distribution of the Lahore Medical College which took place some days before Christmas. The Principal of the College, Colonel F. F. Perry, I.M.S., in his introductory speech said: "There is no need for me to emphasise the fact that medicine is a progressive science and that the teaching of medicine becomes daily more elaborate and complicated. I will not say that the Lahore Medical College and School have been so far *facile princeps* in India, but I think I can justly claim for them that they have been, and are, second to none. In order to maintain this position it is necessary that we should keep up with the times, and in order to do this improvements and changes are essential in the near future." It was not in this admirable little speech that the soft words which do not butter parsnips made their appearance; they became apparent at once in the reply of the Lieutenant-Governor of the Punjab, Sir Denzil Ibbetson. "I have always regarded," he said, "the diffusion of medical and surgical knowledge as one of the best things we have done in India, and one great advantage attaching to medical education in this country is that it stands absolutely apart from all political currents. I should like to see the work enormously extended. We have been told by Colonel Perry of the growth and development of the College in the last 50 years, but I should like to see five times the present number of students in attendance. I should like to see competent medical aid provided for every class of the population, and indeed for every individual who desires to avail himself of it, but if this is to be achieved we must mainly rely upon Indian agency for the expansion. What India particularly wants in this direction at present is not more official medical officers but more private medical practitioners. Trained young men in large numbers are wanted to set up in medical practice on their own account. The process has been begun ...... but I want to see more of the young men who come here to study and to qualify start while in their youth upon a career of private practice instead of fixing their aims upon official employ." So far so good. Nothing could be more admirable than the sentiments which Sir Denzil Ibbetson eloquently expresses. It is quite within the range of possibility that among his hearers there may have been some who looked forward with joy to an announcement that the purse-strings of the sympathetic Governor were about to be relaxed. If such there were they soon were sadly disillusioned. "Well now, gentlemen," continued the speaker, "Colonel Perry has told us of changes and improvements and has asked for my interest and sympathy. I promised him both in the fullest measure. ...... But, gentlemen, you are all well acquainted with the serious nature of the present financial situation. This is a lean year ...... there is practically no hope that the Government will be able to provide a large sum of money for improvements in this College during the present financial year, and probably not during the next financial year, but while I am obliged to say that let me also say that the proposed changes undoubtedly have my sympathy and interest, and that when the time comes I will do my best." These were soft words but it seems a pity that the leading medical college must be starved.

A TELEGRAM from the Acting Governor of the Gold Coast received at the Colonial Office on Jan. 18th states that on Jan. 17th there were 4 deaths from plague. The total number of natives in hospital is 9, while 41 are isolated. A further telegram states that on Jan. 18th there was 1 death from plague. 17 natives were in hospital and 41 were still isolated. The Department of Public Health for Queensland in a bulletin dated Dec. 14th, 1907, states that a case of plague at Cairns was reported on Nov. 23rd, 1907. The patient died on Nov. 30th. The case which occurred previously to this one at Cairns was reported on Oct. 8th, 1907.

THE MEDICAL INSPECTION OF SCHOOL CHILDREN.—At a meeting of the Taunton town council held on Jan. 14th it was decided to appoint Dr. H. J. Alford, the medical officer of health, to be medical inspector of the school children of Taunton at a commencing salary of £100 per annum.—A joint conference between representatives of the Monmouthshire education committee and the sanitary committee of the Monmouthshire county council was held at Newport on Jan. 17th to consider the question of the medical inspection of children attending the Monmouthshire schools. After some discussion it was decided to recommend the appointment of a chief medical officer with two assistants to carry out the work.

fleas being caught in the houses and plague rats being found from time to time. In all 45 per cent. of the houses of that section of the village were shown to be plague-infected; by the nature of the experiment contact between the guinea-pigs in the different houses was excluded. Among the rats the infection persisted for two months and took six weeks to travel 300 feet. The authors conclude that the infecting agent was slowly disseminated among the guinea-pigs by plague-infected rats.

2. *Wadhala Village* (population 1500).—The observations made here were incomplete. In the early part of the epidemic season two cases of plague were imported from Bombay and died in the village without giving origin to any other human cases or any epizootic. Subsequently a number of human cases occurred, some of which were in close association with dead rats which could not be obtained for examination or with rats proved to be plague-infected.

3. *Parel Village* (population 3525).—During the period of observation 28 cases of human plague occurred in this village. Five of these were definitely associated in time and place with a limited epizootic among Mus rattus confined to one corner of the village. Ten cases were brought to Parel already infected; in six the probable source of infection could not be determined, the diagnosis being doubtful in one case, while seven were probably infected outside the village as they had recently visited places where rat plague was known to be present. An interesting observation is detailed as follows:—

Cases 14, 15, 16, 18, 19, 24, and 25 were all employed at a cotton spinning mill in the Sewri section of Bombay. Dead rats had been found in several parts of this mill, but especially in the mixing department, where cases Nos. 14, 15, 18, and 19 worked. Two of these men had thrown out the rats. Cases 16 and 24 were employed in other parts of the same mill. Case 24 lived with her son (25) who occasionally visited the mill with his mother. The woman had noticed dead rats in the go-down where she worked. All these cases and three others investigated by us who lived in other parts of Bombay but worked in this mill were attacked between the 30th April and 10th May. An interesting experiment was done in the mixing room in the mill. On the 12th May two guinea-pigs were placed in it; they were examined for fleas on the 14th May. On one guinea-pig 108 and on the other 160 rat fleas were captured. After the fleas had been removed the guinea-pigs were taken to the laboratory and isolated. They remained healthy. The fleas were transferred to a fresh guinea-pig confined in a flea-proof cage in the laboratory. This guinea pig died of plague on the 20th May. The mixing room was thus proved to be infective. It is important to note that these cases lived in different parts of Parel village and that we could obtain no evidence of a rat epizootic at their homes which did not prove infective to guinea-pigs. The infection therefore may reasonably be attributed to the mill in which they worked.

The infectivity of the houses in which plague cases occurred was investigated experimentally by means of guinea-pig flea traps. Though one of the imported cases infected the house in which she died, as shown by the capture of plague-infected fleas therein, none of them gave origin to any further human cases or to any epizootic among the rats. A number of interesting data are given relative to the prevalence of rats in this village which was very thoroughly trapped for nearly 12 months. This systematic trapping appeared materially to reduce the rat population.

4. *Worli Village* (population 2508).—Systematic trapping for a year appeared to reduce the rat population to approximately one quarter of the original number. No epizootic occurred among the rats and only three cases of human plague. It is probable that all these contracted the infection outside the village. In two of the cases evidence was obtained which pointed to infection so introduced having spread in one instance to a guinea-pig and in the other to a rat.

XXIV.—*General Considerations Regarding the Spread of Infection, Infectivity of Houses, &c., in Bombay City and Island.*

With regard to the spread of infection within houses the authors point out that the universal experience in plague hospitals has been that infection is not, except in pneumonic cases, communicated from the sick to the healthy attendants and others. Their own observations show that guinea-pigs running free in the plague wards do not collect rat fleas nor do they contract plague; that guinea-pigs do not contract plague when kept in a flea-proof hut in close contact with the bedding of plague cases removed daily for several weeks; and that the urine and fæces of acute plague cases are not infective to guinea-pigs by cutaneous inoculation. Their observations in Bombay villages tend to show that infection efficient to start an epidemic is not brought to a place in the persons of those sick of plague unless it is first effective in starting an epizootic. They also point out that in Bombay city comparatively few houses yield more than one or two cases. Recalling the experiments already published,[2] showing that plague is by no means easily transmitted from rat to rat by means of the human flea and that the degree of septicæmia found in the human cases is much less than in infected rats, they conclude that the transmission of infection from man to man by Pulex irritans is probably a very infrequent occurrence. The observations made in the village of Sion show that a widespread dissemination of infection in houses may result from an epizootic in the rats when direct contact with sick occupants of the house is rigidly excluded. In general, therefore, they reach the conclusion that contact with plague cases plays no part in the spread of the epidemic.

Plague is admittedly a place infection—i.e., a house or a room in a house may be definitely infective. Seeing that persons suffering from plague and their excreta are not infective and that, as was previously shown, the air and soil of plague-infected houses do not *per se* convey plague, much support is rendered to the view of the Commission that infection is contracted by man from the rat by means of rat fleas and that the infectivity of houses is due to the presence within them of infected rat fleas. It is also of opinion that plague may easily be transmitted to a distance by the same means.

During the whole of the work in Bombay no evidence was obtained suggesting that plague among the common or domestic animals (other than rats) was of any practical importance. Natural plague was observed only in guinea-pigs, rabbits, and monkeys (a limited epizootic in the Victoria Gardens) with one doubtful case in a cat.

XXV.—*Observations in the Punjab Villages of Dhand and Kasel.*

The villages of Dhand (population 1920) and Kasel (population 3938) were kept under close observation for a year from December, 1905. The general methods of inquiry were the same as those used in Bombay, and these villages were selected as representing isolated communities which had experienced an epidemic of plague in each year since its introduction into the district in 1902. An analysis of the data showed that plague did not tend to recur in the same houses year after year. The rats were practically all Mus rattus with a few Nesokia bengalensis; no Mus decumanus were found. In these villages Mus rattus is both a house and a burrowing rat. No relation was found between the breeding season of the rats and the prevalence of epizootic plague. As in the Bombay villages, extensive systematic trapping appeared to reduce materially the rat population. Of the fleas caught on the rats 98 per cent. were Pulex cheopis; the average number taken on each rat varied from 12·6 in April during the onset of the plague epizootic to 2·2 in August and September in the off-plague season. During the period November to April about 2 per cent. of the fleas were Ceratophyllus fasciatus (the common rat flea of Europe); none were found during the rest of the year.

Dhand village.—No definite origin could be ascertained. Acute rat plague (28 cases) slightly preceded human plague (32 cases) and the two show a close association in time during their prevalence from February to May. 11 rats suffering from chronic plague were taken between December and June. Of the human cases 22 inhabited 18 houses in which, or in the vicinity of which, plague rats had been found before or at the time of the occurrence of the cases. The other ten cases inhabited eight houses and no definite association with plague rats was demonstrated. Three of these eight houses (four cases) were, however, shown by guinea-pig experiments to contain infected rat fleas and two more of the cases lived close to these houses. Two of the remaining cases were clearly imported (late in the epidemic). The authors consider their failure to trace a more intimate association between rat and human plague to be largely due to the limitations of the available methods of finding plague rats.

Kasel village.—Here again the epizootic appeared to arise spontaneously though several of the neighbouring villages, including Dhand, were already infected. Acute rat plague was first discovered three days before the first indigenous human case and the close correspondence in time between the epizootic (238 acute plague rats) and the epidemic (75 cases) from April to July is well shown in a curve. 23 rats suffering from chronic plague were caught between April driven into the surface of the ulcer which has been previously cleaned. If the ulcer is small and the application is carefully and thoroughly done, once only will be found sufficient to cause its disappearance. It is probable that it will be applied successfully in other conditions such as ringworm, and lupus vulgaris would appear to be one likely to be influenced favourably by the local introduction of some ion prejudicial to the life of the bacillus. There should also be a large field open to investigation in regard to its use in gouty and rheumatic deposits. Theoretically an objection to this method is that the substance introduced would be washed away by the circulation before it had penetrated very deeply. While this is no doubt true to a certain extent it is none the less true that the process at times enables a more pronounced local action to be produced of, say, iodine than is possible by the administration of iodides in the usual way.

ROYAL COLLEGE OF SURGEONS OF ENGLAND: THE LECTURE ARRANGEMENTS FOR 1908.

THE annual course of lectures to be delivered at the Royal College of Surgeons of England will commence on Feb. 10th and will be continued on each Monday, Wednesday, and Friday until March 20th. The lecture hour will be 5 P.M. each day. Erasmus Wilson lectures: Mr. S. G. Shattock will deliver one lecture on Ovarian Teratomata on Feb. 10th; Dr. J. W. H. Eyre, one lecture on the importance (surgically) of the Pyogenetic Activities of Diplococcus Pneumoniæ on Feb. 12th; and Mr. L. S. Dudgeon, one lecture on Infection of the Urinary Tract due to Bacillus Coli, on Feb. 14th. Hunterian lectures: Dr. Victor Bonney will deliver three lectures on a Study of the Connective Tissues in Carcinoma and in Certain Pathological Conditions preceding its Onset, on Feb. 17th, 19th, and 21st; Mr. Donald J. Armour, three lectures on the Surgery of the Spinal Cord and its Membranes, on Feb. 24th, 26th, and 28th; Dr. F. C. Shrubsall, three lectures on the Physical Anthropology of the Pigmy and Negro Races of Africa, on March 2nd, 4th, and 6th; Mr. A. Ralph Thompson, two lectures on the Anatomy of the Long Bones relating to certain Fractures, on March 9th and 11th; and Mr. W. S. Handley, one lecture on the Natural Cure of Cancer, on March 13th. Arris and Gale lectures: Dr. F. A. Bainbridge will deliver one lecture on the Pathology of Acid Intoxication, on March 16th, and Mr. M. Greenwood, jun., two lectures on the Physiological and Pathological Effects which Follow Exposure to Compressed Air on March 18th and 20th.

THE LAHORE MEDICAL COLLEGE.

THERE is a quaint old saying or proverb to the effect that "Soft words butter no parsnips." Doubtless the apothegm is an onomatopoetic corruption of another in a different language, couched in more dignified terms and possibly possessing a different meaning, but be this as it may the modern meaning was well exemplified at the annual prize distribution of the Lahore Medical College which took place some days before Christmas. The Principal of the College, Colonel F. F. Perry, I.M.S., in his introductory speech said: "There is no need for me to emphasise the fact that medicine is a progressive science and that the teaching of medicine becomes daily more elaborate and complicated. I will not say that the Lahore Medical College and School have been so far *facile princeps* in India, but I think I can justly claim for them that they have been, and are, second to none. In order to maintain this position it is necessary that we should keep up with the times, and in order to do this improvements and changes are essential in the near future." It was not in this admirable little speech that the soft words which do not butter parsnips made their appearance; they became apparent at once in the reply of the Lieutenant-Governor of the Punjab, Sir Denzil Ibbetson. "I have always regarded," he said, "the diffusion of medical and surgical knowledge as one of the best things we have done in India, and one great advantage attaching to medical education in this country is that it stands absolutely apart from all political currents. I should like to see the work enormously extended. We have been told by Colonel Perry of the growth and development of the College in the last 50 years, but I should like to see five times the present number of students in attendance. I should like to see competent medical aid provided for every class of the population, and indeed for every individual who desires to avail himself of it, but if this is to be achieved we must mainly rely upon Indian agency for the expansion. What India particularly wants in this direction at present is not more official medical officers but more private medical practitioners. Trained young men in large numbers are wanted to set up in medical practice on their own account. The process has been begun ...... but I want to see more of the young men who come here to study and to qualify start while in their youth upon a career of private practice instead of fixing their aims upon official employ." So far so good. Nothing could be more admirable than the sentiments which Sir Denzil Ibbetson eloquently expresses. It is quite within the range of possibility that among his hearers there may have been some who looked forward with joy to an announcement that the purse-strings of the sympathetic Governor were about to be relaxed. If such there were they soon were sadly disillusioned. "Well now, gentlemen," continued the speaker, "Colonel Perry has told us of charges and improvements and has asked for my interest and sympathy. I promised him both in the fullest measure. ...... But, gentlemen, you are all well acquainted with the serious nature of the present financial situation. This is a lean year ...... there is practically no hope that the Government will be able to provide a large sum of money for improvements in this College during the present financial year, and probably not during the next financial year, but while I am obliged to say that let me also say that the proposed changes undoubtedly have my sympathy and interest, and that when the time comes I will do my best." These were soft words but it seems a pity that the leading medical college must be starved.

A TELEGRAM from the Acting Governor of the Gold Coast received at the Colonial Office on Jan. 18th states that on Jan. 17th there were 4 deaths from plague. The total number of natives in hospital is 9, while 41 are isolated. A further telegram states that on Jan. 18th there was 1 death from plague. 17 natives were in hospital and 41 were still isolated. The Department of Public Health for Queensland in a bulletin dated Dec. 14th, 1907, states that a case of plague at Cairns was reported on Nov. 23rd, 1907. The patient died on Nov. 30th. The case which occurred previously to this one at Cairns was reported on Oct. 8th, 1907.

THE MEDICAL INSPECTION OF SCHOOL CHILDREN.—At a meeting of the Taunton town council held on Jan. 14th it was decided to appoint Dr. H. J. Alford, the medical officer of health, to be medical inspector of the school children of Taunton at a commencing salary of £100 per annum.—A joint conference between representatives of the Monmouthshire education committee and the sanitary committee of the Monmouthshire county council was held at Newport on Jan. 17th to consider the question of the medical inspection of children attending the Monmouthshire schools. After some discussion it was decided to recommend the appointment of a chief medical officer with two assistants to carry out the work.

your letter of the 25th ult. was passed. Miss E. S. Kerrison, one of the guardians of West Ham, stated that "they had excellent wards, and many applications for training could be entertained if they were allowed to do so." "They had the wards and the women, but not the authority." This statement passed unchallenged at the meeting and no doubt had its influence on the passing of the resolution. The real fact was, as pointed out by the medical officer of the union in a letter to the *Poor Law Officers' Journal* of Dec. 7th, that the West Ham workhouse had been recognised by the Board as a training school for more than two years.

An analysis of the list of approved training schools as it stands at present, differentiating between Poor-law and non-Poor-law institutions, shows the following result:—Poor-law: London, 6; England (except London), 13; Wales, 1; total, 20. Non-Poor-law: London, 12; England (except London), 21; Wales, 1; total, 34. In addition to these the medical officers of the following Poor-law institutions have been recognised as teachers of midwifery, thus enabling the training of midwives to be carried on under precisely the same conditions as if the institution itself had been approved as a training school: Blackburn, Blandford, Brentford, Burton-on-Trent, Christchurch, Epsom, Halifax, Hastings, Kingston-on-Thames, Llanelly, Merthyr Tydfil, Newbury, Portsmouth, Prescot, Preston, Reading, Rotherham, Southampton, Swansea, Walsall, Wolverhampton, Woodstock, Worcester.

During the year 1907 the 20 approved Poor-law institutions and the 23 recognised Poor-law teachers have sent up 139 candidates to the Board's examinations. The 34 non-Poor-law institutions and the 64 teachers have sent up 1626. A scrutiny of the list of candidates shows that of the Poor-law institutions one, and of the Poor-law teachers seven, have never sent up a single candidate for examination. In these cases the Board concludes that either the material for training midwives does not exist, or that the facilities already accorded by the Board have not been fully utilised. Since Jan. 1st, 1907, 15 Poor-law institutions have applied to the Board to be approved as training schools. Of these applications three have been granted, ten refused, and consideration of the other two is still pending. A list of the applications refused, with the number of deliveries per annum in each institution, is as follows:—

Name of Institution.	Deliveries per annum.
Ashton-under-Lyne Union Hospital	23
Auckland Union Infirmary	8
Dewsbury Union Workhouse Infirmary	20
Gateshead Union Hospital	34
Kingston Union Infirmary	63*
Lincoln Workhouse	18
North Bierley Union Infirmary (Bradford)	16
Sculcoates Workhouse Infirmary (Hull)	37
Stepping Hill Poor-law Hospital (Stockport)	39
Wycombe Union Infirmary	10
	268

* Medical officer recognised as teacher.

It appears to the Board to be undesirable to accord the name of Training School to an institution which cannot within the Rules train more than two pupils per annum. In such cases where there is evidence of an effective possibility of adequate training, the policy of the Board is to recognise the medical officer as a teacher, a course which in no way limits the opportunity of the guardians for the purpose of training. I am to add that, while the Board is deeply conscious of the necessity of according due facilities for the training of midwives where adequate guarantee exists for compliance with the Rules, it is very doubtful whether Poor-law institutions are authorised to undertake the training of any pupils other than their own probationers. If the Board had granted all the applications for approval as training schools made during the current year by Poor-law institutions the list shows that the maximum addition to the number of candidates at the examinations would have been 13, trained under conditions inferior to the standard which the Board has endeavoured to maintain.

I am further to submit that, in view of these facts, there is no ground for the suggestion that the policy of the Board has operated to limit the effective employment of methods and material at present available for the training of midwives. In conclusion, I am to state that, in the opinion of the Board, a division of authority, such as is contemplated by the resolution of the Association of Poor Law Institutions in England and Wales, would be prejudicial alike to the due training of midwives and to the public interest.

THE VACCINATION ORDER OF 1907.

SOME difficulty has recently arisen amongst public vaccinators in connexion with Article III. of the Vaccination Order of 1907 in so far as it affects the contracts entered into with their respective guardians. It is well known that the Vaccination Order of last year was largely aimed at lowering the fees to which these officers were entitled, for it laid down that these fees should in future be set forth in an "instrument" or legal document having relation to the conditions of individual districts and sent to the guardians and public vaccinators concerned. It would appear that many of these officers have signed such an instrument without fully appreciating its significance, having misunderstood the meaning of the section of the Order which governed its issue, and the question of appealing to the Local Government Board has been raised by a number of them. On their behalf the following letter has been sent to that Board by the Association of Public Vaccinators of England and Wales:—

1, Mitre Court Buildings, Temple, E.C., Dec. 18th, 1907.

SIR,—As public vaccinators are continually seeking advice respecting their right of appeal against the "instrument" issued under the Vaccination Order of 1907, the members of my council have directed me to inquire whether I may be granted the privilege of an interview with one of the assistant secretaries or, in the alternative, whether I may be honoured with your advice in writing upon the following points:—

1. As to the procedure to be adopted by public vaccinators who desire to appeal and
2. As to the circumstances under which such appeal arises.

The public vaccinators who desire advice may be divided into the following classes:—(*a*) Those who having been forced by threats of 28 days' notice to accept what they consider inadequate fees have done nothing further. (*b*) Those who have been forced in a similar manner but who have also signed new contracts. (*c*) Those who have, without such compulsion, accepted lower fees, but who are not satisfied and would like to appeal to the Local Government Board, either at once or after an interval, during which they are prepared to give the new fees a fair trial. (*d*) Those who have not agreed with their guardians before Oct. 1st last.

My council is very anxious to know whether an appeal arises upon the issue of the instrument in all of such cases, and if not whether it arises in any, and if so in which of them, and what has to be done by a public vaccinator who desires to appeal to the Local Government Board.

In some cases public vaccinators have agreed with their guardians for a reduced fee on the understanding that it is only for a short period and as a trial, and in those cases the public vaccinators are anxious to know whether, if the guardians refuse to reconsider the matter, they (the public vaccinators) will have a right to appeal to the Local Government Board.

Apologising for troubling you at this length,

I am, Sir, your obedient servant,
(Signed) CHAS. GREENWOOD, Organising Secretary.

The Secretary, Local Government Board.

This letter elicited the following reply:—

Local Government Board, Whitehall, S.W., Jan. 1st, 1908.

Sir,—I am directed by the Local Government Board to advert to your letter of the 18th ultimo and to state that the appeal to the Board provided for in Article III. of the Vaccination Order, 1907, arises in cases in which the vaccination contracts have not been determined and in which the guardians and public vaccinators have failed to agree on the fees to be paid; but that a public vaccinator has no ground of appeal if he has signed the forms agreeing with the guardians as to the fees or has entered into a new contract with the guardians.

A public vaccinator entitled to appeal to the Board should send to the Board a detailed statement of his reasons for declining to accept the fees offered by the guardians.

I am, Sir, your obedient servant,
(Signed) J. S. DAVY,
Assistant Secretary.

C. Greenwood, Esq.

We have carefully studied the Order to which this correspondence refers, which is couched in the usual confusing mass of legal verbiage in which Parliamentary documents seem to seek the concealment of their real meaning. We cannot explain why a document which is nominally intended for the guidance of the common people of England cannot be couched in language which may be readily "understanded of the people," and we can sympathise with those gentlemen who have misapprehended the clause in question, but there is no doubt that if they have signed an "instrument" issued under its authority they have legally bound themselves to accept the conditions of service and remuneration therein contained. Public vaccinators objecting to the terms of the "instrument" submitted to them should therefore appeal to the Local Government Board before signing it or they will find themselves in an unfortunately false position

Looking Back.

FROM

THE LANCET, *SATURDAY*, Jan. 23rd, 1830.

Gun-shot Wounds.—Gun-shot wounds have very commonly been considered as altogether different from wounds of other kinds, as being very peculiar in their nature. The injury which is inflicted by wounds of this nature, is very considerable. The inflammation which they produce in the part is violent; their consequences altogether are very serious. Hence, when fire-arms were first introduced, the effects of these wounds were found so much more serious than those which were ordinarily occasioned by the weapons which were previously employed, that it was supposed that gun-shot wounds were of a poisonous nature. It was suggested that the gunpowder, or the heat of the ball, in some measure affected the wound, and thus that some highly deleterious effect was produced in the injured part. Attempts were therefore made to counteract this deleterious influence by such applications as were supposed to be capable of counteracting heat; the application of turpentine, hot oils, and similar hot and stimulating remedies, were resorted to for this purpose. Writers of modern times, particularly the military surgeons of Europe, have had ample opportunities of observing gun-shot wounds, and of investigating their is, of course, provided the action of the central authority receives the loyal support of the several borough councils.

Among the fevers formerly designated "continued," typhus fever appears to have caused no deaths in London during the year 1906; nevertheless, it is clear from the present report that were it not for the vigilance of the sanitary authorities we should still hear of extensive local epidemics of the disease from time to time. For instance, we learn that in the period referred to four cases of undoubted typhus fever occurred and were removed to hospital, one of which cases was notified as suffering from enteric fever and was apparently isolated as such.

The cases of enteric fever in the metropolis were equal to a rate of 0·3 per 1000 of the population in the year 1906, a rate which corresponds closely to that obtaining in the immediately preceding year. In the year first mentioned Finsbury had the highest death-rate from enteric fever and Chelsea and Stoke Newington the lowest. Of the cases notified to be suffering from enteric fever, we learn that "a portion was found, after inquiry by the medical officers of health, to be incorrectly diagnosed." With respect to those that were accepted as being actual cases of enteric fever, effort was made by medical officers of health to discover the cause of the illness. A considerable number of these were believed to have received infection from elsewhere, some of them having been infected on the continent, whither they had repaired for the summer holiday. Among articles of food believed to have been instrumental in conveying infection cockles are once again frequently mentioned in the reports of medical officers of health, Southend and Leigh-on-Sea being referred to as the source of some of these molluscs. Dr. C. Sanders of West Ham reports an outbreak of not fewer than 52 cases of enteric fever during 1906, a number of the persons attacked having been found by him to have eaten cockles a short time before the onset of the disease. After discussing the views of his colleagues as to the part played by cockles in the spread of infection, Sir Shirley Murphy pertinently remarks: "Whatever view is taken as to the sufficiency of the evidence incriminating the cockles in these outbreaks, the fact remains that the risk of consumption of cockles which have been laid in the Leigh Creek is now well recognised, and any further evidence of injury to London inhabitants from this source must necessarily raise question as to the steps which should be taken in dealing with this matter by public authorities of the localities whose inhabitants suffer in this manner."

(To be continued.)

ROYAL COLLEGE OF PHYSICIANS OF LONDON.

AN extraordinary Comitia was held on Jan. 17th, Sir RICHARD DOUGLAS POWELL, Bart., K.C.V.O., the President, being in the chair.

The consideration of the petition from the London School of Medicine for Women praying for the admission of women to the examinations of the College and of the whole question involved was resumed. On the previous occasion a motion was proposed and seconded "that the petition of the London School of Medicine for Women be granted." To this an amendment had been carried "That it is desirable that such alterations be made in the by-laws as to allow the admission of women to the examination for the Licence only of the College." When this had been put as a substantive motion an amendment had been moved and seconded "that the word 'only' be omitted." This was discussed at some length and the amendment was eventually carried by a large majority. On this being put as a substantive motion a further amendment was proposed to the effect:

> That it is desirable that such alterations be made in the by-laws as to allow the admission of women to the examinations of the College.

This was carried by 74 votes to 33.

The REGISTRAR (Dr. E. LIVEING) then moved a rider which was seconded by the SENIOR CENSOR (Dr. D. FERRIER) and carried *nemine contradicente*:—

> That it is not intended that any action should be taken under the resolution just adopted inconsistent with the agreement between the two Royal Colleges under which the Licence of the one and the Membership of the other are only granted conjointly.

The following communications were received:—1. From the Secretary of the Royal College of Surgeons of England, two letters reporting proceedings of its Council on Nov. 14th and Dec. 12th last. 2. From the Marine Department of the Board of Trade, inclosing a letter from the Governor of St. Helena forwarding a report by Dr. J. J. W. Arnold, the Colonial surgeon, on the necessity of issuing further instructions respecting the treatment of beri-beri and asking the views of the College. The matter was referred to a committee consisting of the President, Sir W. S. Church, Dr. J. F. Payne, Sir Patrick Manson, and Professor R. T. Hewlett. 3. From the Royal Sanitary Institute, inviting the College to appoint delegates to the annual congress of the institute to be held at Cardiff, from July 13th to 18th next. It was resolved to appoint two delegates whose names would be announced at a future meeting. 4. From the Dean of the Faculty of Medicine of the University of Edinburgh, announcing the award of the Murchison scholarship (1907) to James Sutherland Edwards, M.B. Edin.

Sir Dyce Duckworth was re-elected a representative of the College on the Council of Queen Victoria's Institute for Nurses.

A report was received and adopted from the Committee of Management recommending that the Municipal Technical School, Accrington, should be added to the list of institutions recognised by the Examining Board in England for instruction in chemistry and physics.

The committee also recommended that the Borough of Devonport small-pox and fever hospitals should be added to the list of fever hospitals recognised by the Examining Board in England.

The PRESIDENT then dissolved the Comitia.

THE FUTURE OF THE MEDICAL PROFESSION: A FRENCH VIEW.

THE Students' Number of *Le Progrès Médical* for 1907, which was published at the end of the year, contains an article by M. J. Noir upon "The Future of the Medical Profession" which will be interesting to all of us. Our readers will remember that last year we published articles from our Special Commissioner entitled "The Organisation of the Medical Profession in France.[1]" We find that our French colleagues are called upon to deal with much the same difficulties in medical politics as have engaged the attention of the profession in England, and the abstract from M. Noir's paper which we publish below shows (as did the previous account by our Special Commissioner) how some important ethical questions have been solved in France. We learn how our French colleagues, for example, deal with "the right of choice of a medical man by the patient," a matter upon which we have often had to write. We note also "that a medical examination of an injured workman can only take place in the presence of the medical man in attendance, who should have notice by letter two days beforehand." This, again, is a point which has received attention from us, and is one of very great importance to general practitioners. The general remarks of M. Noir on the Socialistic tendencies of modern medical practice will also be read with interest by all British practitioners. We, too, on this side of the Channel have seen recently great developments of the system of the State employment of medicine, and it behoves us to be aware of its professional perils as well as of its advantages.

"It is not amongst its enemies that the medical profession should seek the danger which menaces it; it is in the transformation which it appears called upon to undergo with the times; it is within its own body that the germ of dissociation is likely to arise which will be capable for a time of arresting its healthy growth and of compromising its success. In proportion as the rôle of the medical man has increased and been ennobled, his material position has diminished and has become more and more precarious. The consideration and moral influence which he enjoyed have attracted a larger and larger number of young men to a medical career. The development of general education has further unduly increased the number of students. Medicine is now, indeed, an overcrowded profession. In consequence of this a crisis has arisen, dangerous without doubt, but which will be only transitory, like every crisis, and of little importance if it did not threaten to make the practice of our art evolve in a pernicious manner diseases in the corresponding week of last year. The causes of 22, or 2·6 per cent., of the deaths in these towns last week were not certified or not stated; in the 76 English towns the proportion of these uncertified deaths last week did not exceed 0·9 per cent.

---

[1] THE LANCET, March 30th (p. 911) and April 27th (p. 1190).

HEALTH OF DUBLIN.

The annual rate of mortality in Dublin, which had been equal to 25·5 and 26·0 per 1000 in the two preceding weeks, further rose to 31·2 in the week ending Jan. 18th. During the first three weeks of the current year the death-rate in the city averaged 27·6 per 1000, the rates during the same period not exceeding 18·3 in London and 18·2 in Edinburgh. The 236 deaths of Dublin residents registered last week showed a further increase of 39 upon the numbers returned in recent weeks, and included but three which were referred to the principal epidemic diseases, against ten and four in the two preceding weeks; all these three deaths were referred to "fever," probably enteric. These three deaths from epidemic diseases were equal to an annual rate of 0·4 per 1000, the death-rates from the same diseases last week being 1·5 in London and in Edinburgh. No death in Dublin last week was referred to small-pox, measles, scarlet fever, diphtheria, whooping-cough, or diarrhœa. The 236 deaths from all causes in Dublin last week included 37 of infants under one year of age and 76 of persons aged upwards of 60 years; the number of deaths of elderly persons showed a marked increase upon the numbers returned in recent weeks. Nine inquest cases and seven deaths from violence were registered, and 98, or 41·5 per cent., of the deaths occurred in public institutions. The causes of five, or 2·1 per cent., of the deaths in Dublin last week were not certified; the proportion of these uncertified causes of death last week did not amount to 0·1 per cent. in London but were equal to 2·4 per cent. in Edinburgh.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified: Civil Practitioner J. Kirkwood to be Surgeon and Agent at Helmsdale.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel John C. Haslett is placed on temporary half-pay on account of ill-health (dated Jan. 20th, 1908).

Lieutenant Colin Cassidy, from the Seconded List, to be Lieutenant (dated Jan. 1st, 1908).

Colonel D. Wardrop has been selected to succeed Lieutenant-Colonel H. E. R. James as Commandant and Director of Studies, Royal Army Medical College. The undermentioned have joined at Aldershot and have been posted as follows: Lieutenant R. de V. King and Lieutenant J. C. L. Hingston to the Cambridge Hospital for duty, and Lieutenant J. B. Hanafin to the Connaught Hospital for duty. Lieutenant-Colonel A. E. Tate and Captain H. A. Bransbury have joined the London District for duty. Major M. Boyle has been posted to the Station Hospital, Lucknow, and appointed Specialist in Electrical Science, 8th (Lucknow) Division.

VOLUNTEER CORPS.

Rifle: 3rd Volunteer Battalion, The Northumberland Fusiliers: Henry Smurthwaite (late Captain) to be Surgeon-Lieutenant (dated Nov. 1st, 1907). The Queen's Rifle Volunteer Brigade, The Royal Scots (Lothian Regiment): The undermentioned Surgeon-Captains to be Surgeon-Majors: J. H. A. Laing (dated Oct. 28th, 1907); and J. Pirie (dated Oct. 29th, 1907). 1st Volunteer Battalion, The Prince Albert's (Somersetshire Light Infantry): Supernumerary Surgeon-Major J. M. Harper (Brigade Surgeon-Lieutenant-Cylonel, Senior Medical Officer, Cornwall and Somerset Volunteer Infantry Brigade) to be Surgeon-Lieutenant-Colonel, remaining supernumerary (dated Dec. 21st, 1907). 1st Herefordshire Volunteer Rifle Corps: Arthur Llewellyn Baldwin Green (late Lieutenant) to be Surgeon-Lieutenant (dated Dec. 16th, 1907). 5th Middlesex (West Middlesex) Volunteer Rifle Corps: Surgeon-Captain and Honorary Surgeon-Major Richard Charles Maron Pooley (late 1st Volunteer Battalion, The Duke of Cornwall's Light Infantry) from the Retired List to be Surgeon-Captain, with the honorary rank of Surgeon-Major (dated Jan. 1st, 1908).

ALEXANDRA MILITARY HOSPITAL, PORTSMOUTH.

The Royal opening of the New Alexandra Military Hospital on the southern slopes of Portsdown Hill, near Portsmouth, has been abandoned. The Portsmouth Military Hospital staff will enter into occupation of the new buildings shortly.

THE NEW MEDICAL SERVICE FOR THE TERRITORIAL FORCE.

The Director-General of the Army Medical Service addressed a meeting of medical men at the West Kent Hospital, Maidstone, on Dec. 17th last, upon the new medical service for the Territorial Force. Dr. C. E. Hoar was in the chair and invitations had been sent to all medical officers of Volunteers in the Home Counties Division of the Eastern Command. There was a full and appreciative audience, which included amongst many others Colonel M. W. Russell, D.A.D.G., R.A.M.C., Surgeon-Colonel H. G. Thompson, V.D., Surgeon-Colonel R. T. Cæsar, V.D., Colonel T. F. MacNeece, A.M.S., and Major C. P. Oliver, who carried out the arrangements for the meeting and who was able to announce that although many of the officers invited had not been able to attend, yet all had expressed themselves as accepting the scheme as they had read it in the papers. Sir Alfred Keogh's speech was such as we have reported at similar meetings during his late autumn campaign and there is no occasion to repeat his arguments in detail. He took for his text the capital axiom that the function of the medical service of an army is to maintain the fighting strength of that army in the field and showed the lamentable deficiency of the present volunteer medical arrangements in administration, sanitation, and hospital organisation. He expounded his scheme by which he will be able to retain the services of the most skilled experts for the troops in time of war without burdening them with irksome and useless military training and also indicated how medical men who are unable actually to join the scheme may yet promote it by helping to instruct the members of the new force in sanitation, &c. He called attention to the great advantage which the continental powers have over us in the medical service of their home forces and submitted that we should become equally efficient in this respect. Sir Alfred Keogh very modestly deprecated the general professional opinion that the whole credit of the present scheme rests with him, pointing out that volunteer medical officers had long recognised the great need for reform and that in 1901 those in the north put forward a scheme to this end. Later the British Medical Association also evolved a scheme which was practically the same as that which he was advocating. The speaker was well received and subsequently replied to a number of questions addressed to him regarding administration, discipline, pay, and uniform under the conditions of the new service. Surgeon-Colonel Thompson proposed a vote of thanks and pointed out that although the Director-General disclaimed the credit of originating the proposals, yet he had coördinated them in a concrete form. The success of this meeting is of good augury for the future medical service of the Territorial Force in the Home Counties.

AN INDIAN EDITOR PUNISHED FOR DEFAMATION OF AN OFFICER OF THE INDIAN MEDICAL SERVICE.

Mr. Alfred Nundy and Lala Mool Chand, respectively editor and printer of the *Tribune*, a newspaper published at Lahore, have been fined, the former Rs.250 and the latter Rs.50, with alternatives of simple imprisonment, for defaming Captain W. E. McKechnie of the Indian Medical Service. From a long and elaborate judgment delivered by the judge, Mr. Connolly, we learn that one night in May, 1906, a punkha coolie was found lying dead at his post outside the barracks at Jullundur, and that it was alleged by the father of the deceased that his son had died from a kick given him by a soldier. At an inquest which was subsequently held the cause of death was found to have been double pneumonia, and it was further proved after a careful examination that there was not the slightest trace of physical injury on the body. The presiding magistrate upon this issued an order for the arrest of the deceased's father in order that he might be tried for having given false evidence at the inquest. The occurrence excited considerable attention and in a series of three articles having reference to it the *Tribune* made statements which Captain McKechnie, by whom the *post-mortem* examination was conducted, regarded as libellous. An action for defamation was accordingly brought by that officer against the above-mentioned persons, who in due course were they can provide the practitioner residing far from large centres with the laboratories which, left to himself, he could not seriously organise and which he would not have the leisure to use. Gradually becoming conscious of their power we shall afterwards see them found and maintain, with their own resources, paying hospitals for people of limited means, who require assistance and who often only go into hospital with regret. Thus an end will be put to the principal argument of those who pretend that the doors of the hospital cannot be closed to people of means. Hospital abuse, of which the medical profession complains so bitterly and in consequence of which the poor suffer, would disappear.

But if we ought not to despair of the future of the medical profession we ought also not to forget for one instant that it is at a dangerous turning point in its history. The diagnosis of the disease from which it suffers has been made; it has been given a name, '*functionarism*.' The prognosis is serious. But to combat and even to prevent it we have powerful specifics, which are mutual coöperation, strict cohesion, progressive application of the liberty of confidence, and demonstration by deeds that the first care of the medical syndicates is to put themselves at the service of the sick and of the public interest."

REPORTS ON PLAGUE INVESTIGATIONS IN INDIA

ISSUED BY THE ADVISORY COMMITTEE APPOINTED BY THE SECRETARY OF STATE FOR INDIA, THE ROYAL SOCIETY, AND THE LISTER INSTITUTE OF PREVENTIVE MEDICINE.[1]

THE present report is devoted to an account of the epidemiological observations of the Commission which were made in Bombay city, in four villages in Bombay Island, and in two villages in the Amritsar district of the Punjab. In all places the primary object of inquiry was the relationship of rat plague to human plague. Owing to the necessarily complex nature of the data many of the important facts brought forward cannot be condensed into a short summary.

XXI.—*Digest of Recent Observations on the Epidemiology of Plague.*

This paper contains an abstract of the observations and opinions which have been published during the last ten or 12 years on the connexion between rat and human plague, the mode of infection, manner of spread, &c.

XXII.—*Epidemiological Observations made in Bombay City.*

The Commission made an exhaustive inquiry into plague in rats and men in Bombay city over a period of 16 months. The period dealt with in this report is the last *12 months of* the whole investigation (October, 1905, to September, 1906). With the coöperation of Dr. J. A. Turner and his sanitary staff more than 117,000 rats were collected and examined for plague infection in the laboratory at Parel; nearly 18,000 were found infected. At the same time, nearly all the cases of human plague (more than 10,000) in the city were inquired into with the view of ascertaining the probable mode and place of infection, &c. The density of both rat and human plague in Bombay was, however, so great that the Commission found itself unable to draw any very definite conclusions with regard to these points which were more satisfactorily investigated in the smaller village communities. The large numbers in Bombay, on the other hand, show the broad temporal and geographical relations between plague in rats and in men better than the smaller epidemics in limited communities.

By far the most abundant and important rodents in Bombay city are Mus rattus and Mus decumanus. The habits and distribution of the two species differ, for while Mus decumanus lives for the most part outside houses in sewers, stables, &c., Mus rattus is essentially a house rat and abounds in the most intimate relationship with the people. Both are subject to plague; but the percentage of Mus decumanus (18·8 per cent.) found infected was twice as great as Mus rattus (9·5 per cent.). The authors point out in this connexion that the former species usually harbours twice as many fleas as the latter (e.g., in April, 1907, an average of 13·9 fleas per live rat was found in 306 Mus decumanus examined, as against 5·2 per rat on 1911 Mus rattus), while their susceptibility to plague experimentally transmitted by fleas is the same. The breeding season of both species was examined by recording the number of pregnant females and the number of young rats caught week by week; no correlation between the breeding season and epizootic plague was obtained.

Acute plague in both species of rat as well as in man occurs in Bombay city throughout the year; the rat epizootic appeared to begin simultaneously in many parts of the city and no particular focus of origin could be ascertained for the epizootic or the epidemic. It is shown that the general intensity of rat plague corresponds to the intensity of human plague in the different sections of the city: eight sections showed from 1·0 to 3·1 plague rats per building actually obtained and a plague death-rate from 10·7 to 17 per mille, while in the other six sections the plague rats per building were 0·6 or less and the mortality 3·6 to 13·1 per mille. The minute details of the spatial relations between rat and human plague were, for reasons already alluded to, difficult to make out; the general coincidence is illustrated by a series of monthly maps of one district.

The close correspondence in time and relative intensity at different times of the epizootics and epidemic is well shown in a series of curves. That for the whole of Bombay city shows that the beginning of the epizootic in Mus decumanus precedes the epizootic in Mus rattus by about 16 days, and that the epizootic in Mus rattus comes on some 25 days before the rise of the human epizootic. This is confirmed by a series of similar curves for 12 districts of Bombay taken separately. The authors point out that these intervals are not inconsistent with the hypothesis that the flea is the transmitting agent from rat to rat and from rat to man, and they conclude that the epidemic is directly attributable to the Mus rattus epizootic which in its turn takes origin in the Mus decumanus epizootic.

In a statistical analysis of these data, printed as an appendix, Mr. M. Greenwood shows that the correlation between human plague and plague in Mus rattus is of very high order (0·8801 ± 0·0184); he also reaches the important conclusion that the correlation between plague in man and in Mus decumanus (which reaches the large figure of 0·7481 ± 0·036) is probably spurious, depending on the correlation between plague in Mus decumanus and in Mus rattus (which is still higher: 0·945 ± 0·00875).

The paper concludes with a review of the sanitary circumstances of Bombay city in their relation to the prevalence of plague. The authors show that conditions of housing, ventilation, conservancy, and the like can only be considered factors of importance in so far as they encourage the rat population and bring it into more intimate relationship with the people. Even when the people live in well-constructed buildings free from sanitary defects (as in the municipal tenement buildings) they suffer severely from plague owing to their being perfectly agreeable to allow rats to live and to breed in their rooms.

XXIII.—*Observations made in Four Villages in the Neighbourhood of Bombay.*

The villages of Sion, Wadhala, Parel, and Worli in Bombay Island were kept under continuous close observation and were systematically trapped for rats. In Parel there is a sewerage system and Mus decumanus occurs occasionally; Mus rattus, however, greatly predominates and is the *only* species found in the other three villages. No cases of human plague occurred outside the epidemic season. In Sion, Parel, and Worli no plague rats were found during the same period; in Wadhala (where some of the attendants at the Parel laboratory were living) a single rat suffering from acute plague was caught in August. The inhabitants of all four villages are in more or less constant communication with Bombay city.

1. *Sion Village* (population 950).—The origin of plague in this village in January, 1906, could not be definitely ascertained; the available evidence points to the infection having been imported on or about the person of a woman who came from an infected quarter of Bombay. Human plague began soon after, and in the same block of houses as, the occurrence of a dead rat. The inhabitants then evacuated that part of the village and were replaced by guinea-pigs in cages in each house which were kept under careful observation. Plague gradually spread from the original focus through the village, the guinea-pigs dying from plague, plague infected

---

[1] Third report: Journal of Hygiene, vol. vii., pp. 693-985, with 23 plates, 67 maps, and 19 charts. Accounts of the previous reports will be found in THE LANCET, Nov. 3rd, 1906, p. 1233, and July 27th, 1907, p. 245.

variation in the tautness of those non-elastic lungs during each respiration.

In his former letter he assumed the non-adherence of the pleuræ and we now get several other assumptions; I should have preferred facts. He thinks his "purpose is equally well served by taking an actual case in which the pleuræ are adherent. In such a case the traction which the lungs exert on surrounding structures is considerably in excess of the normal and this excess is partly due to the contraction of the scar-tissue but still more to the preponderating action of the inspiratory muscles." I think he might offer some proof of all these statements, and this he tries to do by saying that "in fibroid phthisis the inspiratory muscles do act powerfully, as he can assert from personal observation," but this is no proof that there is increased *tautness* of the lungs and consequent lowered intrathoracic pressure. In asthma and emphysema the inspiratory muscles, both ordinary and extraordinary, may pull and tug and struggle and strive to get air into the chest, but the whole time the intrathoracic pressure may be positive, and Dr. Harry Campbell might tug and pull and push at Cleopatra's Needle till he was black in the face, but he would not make the slightest impression on it. In fibroid lungs there may be a slight fall in the intrathoracic pressure during inspiration, but in advanced cases there is nearly always a positive pressure in expiration and then the blood is not "sucked in." The variations in such pressures only amount to a few millimetres of mercury. What an enormous difference there is between this and the "suction" of healthy elastic lungs. Dr. Campbell ought to be able to produce in Müller's experiment a negative intrathoracic pressure of 70 or 80 millimetres of mercury and a person with fibroid lungs could not do a tenth part of this. What is the use of discussing why a fish should not displace water or how strongly acting inspiratory muscles drag out the chest and with it make *taut* the adherent lungs which thus exert "more traction on circumjacent parts than normal highly elastic lungs." Try and you will find that the fish does displace water, and the lungs are not taut, and the intrathoracic pressure is not lowered. When Sir Frederick Bramwell and some other members of the capital sentences committee discovered that ropes stretch much more than is usually anticipated, and that there is great variation in the stretch of different ropes according to their constitution, and the amount of strain to which they are submitted, and also in the same rope in different circumstances and according to the amount of moisture which it contains, I was asked by the Home Office if I could devise a method of estimating the elasticity of any rope. I did not retire to my study and work out the coefficient of elasticity and what should but what probably would not happen. I determined the *vis viva* or energy which I considered necessary, and then under a strain of a given number of foot-pounds I determined the stretch, and I had no difficulty in devising a method of measuring the length of unstretched rope which would allow of a given energy. So far as I know, my method is still in force, at least, it was when I left the prison service.

He again says that "in many cases of fibroid phthisis the mean size of the thorax is increased, and this in spite of the fact that the lungs are less than normally yielding to a stretching force. How could such an increase be effected but by supernormal activity of the inspiratory muscles?" I always thought that fibroid tissue occupied less space than the portion of the lung which it replaced. I am afraid there is some confusion in Dr. Campbell's mind between fibroid tissue and the accompanying emphysema. We are not at present discussing the causes of emphysema, but only Dr. Campbell's non-existent increased tautness of fibroid lungs, so we need not pursue this point further, but I might refer Dr. Campbell to the extremities and ask him to inquire why his heightened tautness of the lungs should allow the finger ends to become bulbous.

He says: "What, I would ask, has the average intrapulmonary pressure got to do with the stretching of the lungs when the pleuræ are adherent? Manifestly nothing whatever." The question and answer coming from a physicist are really very funny. Does he not know that whether the pleuræ are adherent or not the thoracic parietes intervene between the external atmosphere and the lungs, and any force which expands the thorax beyond the expansile power of the lungs must exercise a power of 15 pounds to the square inch, and this the inspiratory muscles could not do over such a large surface as the chest though they tugged and pulled like Dr. Campbell at Cleopatra's needle? The inspiratory muscles, like Dr. Campbell, often expend a lot of useless energy. How often do we grieve at the struggles of a poor asthmatic doing nothing? Regarding his remarks about the piece of cord, the root of the lung, the visceral pleura, &c., he forgets that every time the cord is stretched in inspiration it is relaxed in expiration; healthy elastic lungs remain always elastic and taut and in direct proportion to the manifestation of their elasticity their tautness and the intra-thoracic negative pressure are increased.

I shall not now dwell on his remarks on his interesting lectures to which I referred, as I shall probably read them again when I get more leisure—not having done so since 1904—but he need not flatter himself that they have met with general acceptance because they have hitherto passed uncriticised, though I think this is not strictly accurate, because I believe, if my memory serve me rightly, and it does not often fail me, that about July, 1904, I expressed to Dr. Campbell a somewhat similar opinion to that recorded by me in your pages. *Hinc illæ lachrymæ.* Notwithstanding Dr. Harry Campbell, the tautness of the lungs depends on their elasticity and the pressure of the air within them, hence I have arrived at the point from which I started, the winning post. *Magna est veritas, et prævalebit.*

I am, Sir, yours faithfully,
JAMES BARR.

Liverpool, Jan. 12th, 1908.

To the Editor of THE LANCET.

SIR,—In the discussion which has lately taken place under the above heading in your columns between Sir James Barr and Dr. Harry Campbell it appears to me, as in so many debated subjects, there is something to be said from both points of view. The question would, however, be materially simplified by defining exactly what is meant by "elasticity" before proceeding to discuss it. Elasticity is the property of a substance in virtue of which it tends to return to its original form and condition after distortion by a force; and it is measured quantitatively by the amount of force required to produce a given distortion in a given volume, or unit, of the substance. Thus steel is more elastic than ivory, and ivory than rubber. Rubber yields considerably to a small force and is therefore comparatively inelastic. It possesses the quality of elasticity to a striking degree but in a low measure.

It is important to remember that elasticity is a property fixed in amount for any substance. Distortion may render it evident but does not increase it. Like moral qualities in man, temptations may exhibit them, but the tried man was a gentleman or honourable before his trials, and if the latter be doubled he is not double the gentleman or double the saint. Sir James Barr is certainly in error where he says in his letter of Dec. 21st, "The more taut or stretched (the lung) the greater will be its elasticity or tendency to recover its form after being stretched." Its elasticity and tendency to recover cannot be increased by stretching; it was inherent in it and fixed in quantity from the first. The tendency of a cat to return home is as great when asleep on the hearth as when lost in the woods; and the unstretched lung of an unborn babe is as elastic as that of the expanded lung of the newly born infant. In the one case the elasticity is dormant, and in the other called into play, but increased *never*.

In considering the forces producing a negative pressure in the pleural sacs there is less objection to Sir James Barr's statements: "In health there is a slight negative pressure in the pleuræ owing to the elasticity of the lungs," and "the elasticity of the lungs tends to separate the pleural surfaces." It is, however, to these statements Dr. Harry Campbell so strongly objects, apparently because of the very restricted sense in which they are true. When an infant first breathes it is the expansion of the chest walls under muscular action which tends to create an intrapleural space of lowered pressure and into this the lung simultaneously expands, because the pressure of the air entering by the windpipe into the lungs is greater than the reduced pressure beneath the thoracic walls by the amount the muscular inspirations can reduce it. In this way the negative pressure in the pleural sacs is created by muscular effort and not by elastic recoil of the lungs. It would be even greater, as Dr. Campbell contends, if the lungs did not expand. It is their expansion which limits the fall of pressure in the pleural sacs. By following the chest expansion the lungs allow the visceral pleura to press on the parietal with a force equal to the whole atmospheric pressure, less that which the elastic recoil of the lungs can support and neutralise.

and December. The 75 human cases occurred in 67 houses (total houses in village 808); in the houses which furnished single cases there were 273 "contacts," of whom only 18 had been inoculated; none of these 255 susceptible persons contracted plague. 53 of the cases were definitely ascertained not to have been in contact with other plague cases. Of the 75 human cases, four were imported, 25 occurred in houses in which plague rats had been found, 36 in houses in the immediate vicinity of which plague rats had been found, and of the remaining ten cases six had visited at houses in which plague rats had been found, three lived in houses in the vicinity of which plague rats were found some days after they fell ill, and one was a doubtful case of plague.

Experiments in plague houses in Dhand and Kasel.—A number of experiments were carried out in these villages similar to those done in Bombay[3] showing that the infective agent in the houses was infected rat fleas. In 49 plague-infected houses guinea-pigs were allowed to run free for about 18 hours; in nine instances they afterwards died from plague. Three times as many fleas were caught on the guinea-pigs in plague-infected as in not plague-infected houses, and five times as many in houses which proved infective to guinea-pigs as in those not infective. Fleas found on guinea-pigs or rats in plague houses were transferred to guinea-pigs in flea-proof cages in the laboratory; in 10 out of 31 experiments the fresh guinea-pigs died from plague. In 51 experiments guinea-pigs, unprotected and protected with fine wire gauze or with "tangle toes," were placed in plague houses; a single flea was found on four of the protected animals, none of which died from plague; from one to 75 fleas were found on 34 of the 51 unprotected animals, six of which died from plague. Nearly 90 per cent. of the fleas caught on the "tangle toes" were rat fleas (the rest being cat fleas), and of 55 dissected the stomach contained plague bacilli in three.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

A QUARTERLY meeting of the Council was held on Jan. 16th, Mr. HENRY MORRIS, the President, being in the chair.

It was resolved that the election of the conservator of the museum should take place at the ordinary meeting of the Council on Feb. 13th.

It was resolved to approve of the suggested alterations of the Standing Rules relating to the conservator of the museum.

It was decided that during the next three months tea should be served at a charge of 4*d.* per person in the library for readers, or in the common room for readers who are Fellows or Members of the College.

A report was received from the committee on the annual report of the Council, and after consideration it was resolved that the first resolution carried at the annual meeting of the Fellows and Members should be referred back to the committee for further consideration. It was further resolved that the mover and seconder of the second resolution (which reaffirmed the desirability of admitting Members to direct representation on the Council) should be informed that the resolution had been laid before the Council and that the views of the Council upon the question referred to therein would be found in the last annual report of the Council. No action was taken with regard to the third resolution.

It was resolved that the mover and seconder of the fourth resolution should be informed that the Council saw no reason to adopt the suggestion. The fourth resolution suggested that when a poll of the Fellows and Members was taken on the question of the admission of women to the diploma of the College a similar course should be taken with regard to the proposal for direct representation of the Members on the Council.

The fifth resolution was a request that the Council should add a hood to the gown already worn by Fellows and Members. The Council resolved not to comply with the request on the ground that a hood was generally distinctive of a degree and was not in general use among colleges of similar standing.

The sixth resolution wished the Council to endeavour to join the work of the College with the University of London (so as to form an Imperial University of London). In reply to this resolution the Council directed that the mover and the seconder should be informed that the matter had been much discussed in the past and that it still occupied the attention of the Council.

Mr. Henry Morris, the President, was appointed Hunterian orator for 1909.

The PRESIDENT reported that he had given evidence on Dec. 20th last before the Home Office Committee on the London Street Ambulances. The evidence was based on a large amount of information which he had obtained from Paris, Berlin, and Boston (Massachusetts). A vote of thanks was given to the President.

Mr. Thomas Bryant was re-elected for three years a representative of the College on the council of Queen Victoria's Jubilee Institute for Nurses.

A committee was appointed to prepare a circular to the Fellows and Members asking their opinion as to the desirability of admitting women to the examinations for the diplomas of the Royal College of Surgeons of England.

CENTRAL MIDWIVES BOARD.

A MEETING of the Central Midwives Board was held at Caxton House, Westminster, on Jan. 16th, Dr. F. H. CHAMPNEYS being in the chair.

A deputation from the guardians and directors of the Coombe Lying-in Hospital, Dublin, consisting of Dr. M. J. Gibson, the Master, a member of the board of the hospital, and the honorary secretary, attended on Jan. 9th and presented a memorial praying the Board to rescind its resolution of Dec. 19th[1] removing the name of the Coombe Hospital from the list of recognised training schools. The memorial was supported by letters from the Very Rev. Canon Scally, the Rev. J. D. Smylie, and Sir Charles A. Cameron, medical officer of health of the city of Dublin, and by a statutory declaration made by the registrar of the Coombe Hospital as to the circumstances in which the board of the hospital first learned of the correspondence between the secretary, the late master, and the registrar on Dec. 30th. The members of the deputation spoke in support of the memorial and Dr. Gibson made application in due form for approval as a teacher. Having fully considered all the evidence and argument submitted to it by the deputation the Board took no action on the memorial but approved Dr. Gibson as a teacher.

Letters were considered from the late Master of the Coombe Hospital, Dublin, and from Messrs. D. and T. Fitzgerald, his solicitors, asking the Board to reconsider its decision not to accept any certificate signed by him in future and the following decision was agreed to: "That the Board declines to reconsider its decision."

A letter was considered from Dr. W. Arnold Evans, medical officer of health of Bradford, as to advertising by midwives and it was decided that Dr. Evans should be informed that the Board has no power to prohibit advertising by midwives.

A letter was considered from a midwife approved by the Board for the purposes of signing Forms III. and IV., inquiring whether her substitute, being a certificated midwife, may supervise cases on her behalf during her absence on a holiday. The Board decided that in the circumstances stated the substitute may supervise the cases, but that the duty and responsibility of signing the certificates remain with the midwife approved by the Board. In case of such substitute acting in this manner it shall be notified on the schedule at the time of signing. The Board then adjourned.

A letter has been addressed to the Lord President of the Privy Council by the secretary of the Central Midwives Board, giving facts and figures in relation to the training of midwives in Poor-law institutions. The letter points out that the public utterances of those who have advocated the transference of the responsibility for the training of midwives in workhouses or workhouse infirmaries from the Central Midwives Board to the Local Government Board appear to indicate an imperfect knowledge of the facts in connexion with the action of the Board in dealing with applications for approval from Poor-law institutions, and considerable misapprehension as to its causes and results. It continues as follows:—

> A conspicuous instance of this occurred at the very meeting of the Association of Poor Law Unions at which the resolution referred to in

[1] THE LANCET, Dec. 28th, 1907, p. 1831.

of health excepting a slight dry cough from which he had been suffering for the past week or ten days. He returned home a little after 6 P.M. and partook of his usual tea, making a good supper a little before 9 previous to turning in for the night at about 9 30 P.M., as from the nature of his occupation he was obliged to keep early hours. At a few minutes to 10 he started out of bed, remarking to his wife that he "felt choked" and ran into the front sitting-room. Here he sank on to a chair and evidently still experiencing intense agony in this situation rolled on to the floor and expired. His intensely cyanosed appearance on rising out of bed so alarmed his wife that I was sent for immediately and arrived at the house it is estimated less than ten minutes after the time when he left his bed. The remarkable severity and rapid dissolution in this case call, I think, for special notice as the experience must be a very rare one. The appearance of the body when first seen by me was as follows. The face was intensely livid and wore an expression of agony, the pupils were very widely dilated, the body was of a natural warmth, supple, muscular, and well nourished and the thorax well formed. Even at this time an abundance of white foam was welling from the mouth and nostrils and there was an escape of a considerable amount of pinkish serous fluid from the mouth. I made the necropsy to-day at 3 P.M., at which the following additional appearances were observed. Post-mortem lividity was strongly marked and the veins all over the surface of the body were greatly distended with very dark blood. The frothy material was still issuing from the nostrils and mouth but the flow of serous fluid had ceased. Each pleural cavity contained about half a pint of reddish serous fluid. The lungs were somewhat voluminous from commencing emphysema at the apex and anterior borders and on division of the bronchi discharged an enormous quantity, over three pints, of reddish serous and frothy fluid, while this could also be squeezed from the lung through the bronchi and all cut surfaces in abundance, the lung tissue then assuming a vesicular character. The larger bronchi and trachea were clear but somewhat congested and otherwise the lung tissue appeared normal. The left ventricle was markedly hypertrophied, the heart weighing 19 ounces, and the aortic valves were somewhat thickened, distorted, and incompetent. The other valves were apparently normal. The aorta was the seat of well-marked atheromatous changes, while the radial and temporal arteries also manifested pronounced thickening and tortuosity. The other organs of the body were in an apparently healthy condition. Microscopically no characteristic abnormal appearance can be detected in the lung. The patient had not been under any treatment. No history of heart or kidney trouble could be obtained. I expressed the opinion that death was due to the sudden strain thrown upon the heart by the rapid engorgement of the lungs.

I am, Sir, yours faithfully,
G. H. C. LUMSDEN, M.B. Aberd.
Brighton, Jan. 17th, 1908.

To the Editor of THE LANCET.

SIR,—In Zola's powerful book "Fécondité" there is a graphic description of the sudden illness of a perfectly healthy young woman whose symptoms began at bedtime, following a wetting from a rain-storm in the afternoon, and who died after intense suffering at 7 o'clock in the morning, "d'une congestion pulmonaire." When the book was published eight years ago a medical friend discussed this case with me. As neither of us was familiar with an acute pneumonia or pulmonary congestion which would cause death in a hitherto healthy adult within seven or eight hours we were at first inclined to class this description among the errors of novelists writing on subjects of which they are ignorant; remembering, however, the notorious accuracy of M. Zola and the mastery of technical detail which he always acquired of any subject on which he undertook to write, and having, moreover, both been in practice sufficiently long to have learnt that we did not know everything, we decided that the novelist was probably correct and our own limited experience at fault.

I now learn that the case described corresponds accurately with those cases of rapidly fatal "acute pulmonary œdema" which have recently been recorded by correspondents in your columns. The clinical picture of the illness drawn by M. Zola is most vivid and accurate and is to be found on pp. 557 to 559 of the ordinary French edition. Perhaps the disease is better known in France than in England, for M. Zola writes of it as of something not very uncommon. The medical interest, in other respects, of this *striking* book is such, and the moral it teaches so impressive, that all might read it with advantage.

I am, Sir, yours faithfully,
Jan. 11th, 1908. C. K.

THE SOCIETY OF MEDICAL PHONOGRAPHERS.

To the Editor of THE LANCET.

SIR,—It is many years since the Society of Medical Phonographers was last mentioned in your columns and we shall be glad if you will allow us to direct attention to the fact that it still exists and still issues its medical periodical in lithographed phonetic shorthand. We believe that many students and members of the profession are ignorant of the society and its efforts to promote the effective use of shorthand in medicine, both in practical work and in research. The honorary secretary will be glad to furnish particulars of the society to any members of the profession or students who may desire to join it.

We are, Sir, yours faithfully,
WILLIAM R. GOWERS, President.
CHARLES W. CATHCART, } Vice-Presidents.

THE CAUSE OF THE PREVALENCE OF ADENOIDS.

To the Editor of THE LANCET.

SIR,—If reliable statistics were available it would, I believe, be conclusively proved that during the last 30 years there has been a remarkable increase in the number of children affected with adenoids. That adenoids have always existed may, no doubt, be correctly inferred from indirect evidence, but on the other hand, evidence has been brought forward to show that until recent years it must have been quite a rare disease. However, as regards what exists at present, I would mention that it is difficult to find evidence of many cases indicating the previous existence of adenoids among people of 40 years of age and upwards, whereas it seems to be comparatively rare to find a family of children without at least one of its members having suffered from the disease. It is not my intention, however, to compare the past with the present. What I want to do is simply to state that without any attempt at selection I took a number of families whose habits I knew with regard to the keeping of open windows in the sleeping apartments of their children. Of those who kept the windows shut at night there were five families, having 26 children in all, and not one of these 26 children had ever suffered from adenoids. While of five families, having 19 children in all, who kept open windows at night throughout the year, eight of these children had suffered from adenoids sufficiently badly to have required operation. Now I do not put any importance on these figures, they are too few to be of any particular value beyond being very suggestive, and it was not on account of them that I was led to think that open windows at night might be an important factor in the causation of the prevalence of the disease. I am writing because I am not in a position to get as full statistics on the subject as seems desirable and I should like particularly to know the effect of cold and damp night air, such as we usually have in England, in the production of adenoids and of its value or otherwise in the treatment of an ordinary cold in the head.

I am, Sir, yours faithfully,
Wimpole-street, W., Jan. 20th, 1908. J. SIM WALLACE.

THE INFECTIVITY OF CANCER.

To the Editor of THE LANCET.

SIR,—I very much regret to find from his letter addressed to you in THE LANCET of Jan. 18th, p. 188, that I have inadvertently misrepresented Dr. Bashford by attributing to him instead of to Messrs. Farmer, Moore, and Walker the statement reported in the *British Medical Journal* of Jan. 30th, 1904, that "malignant new growths were virtually reproductive tissue arising in abnormal situations" and I am nature; so that this part of the subject, and the particular rules applicable to it, are now very well understood. The only peculiarities in gun-shot wounds, arise from the nature of the objects by which the wounds are inflicted, and the degree of force with which they strike the textures of the human body. Balls, bullets, fragments of shells, splinters of stone and wood, and various hard substances of these kinds, are the objects by which the wounds are made, and they are driven with great force against the body; they produce lacerated and contused wounds of the most serious kind; that is, they produce injuries which are attended with very serious local inflammation. The degree of violence with which these wounds are inflicted, differs in different instances. If a gun-shot projectile meets the body directly and in full force, it traverses the part if it be small; or if it be larger, and meet a limb, for example, it probably carries it away. If a small substance meet the body directly, with a less degree of force, it will tear and lacerate the part, break and splinter the bone, producing injuries of this kind according to the degree of force with which it was moving. Sometimes balls or bullets strike the body obliquely; they do not come directly against it, but they strike it at various angles, and, in fact, do not enter the body, but, having touched it, glance off again. Under these circumstances, the soft textures that intervene between the skin and the bone may be divided, and effusion of blood may take place; the bone itself may be broken without the skin apparently being injured. It often happens in battle, that persons are found dead on the field in whom there is no appearance of a wound to account for death; but if the bodies be accurately examined, some injury of this kind will be found to have taken place; and those injuries have been very commonly ascribed to the "wind of the ball." It has been supposed, that a ball which has not struck the body, but has passed very near to it, produces some kind of influence, and that influence has vaguely been ascribed to the "wind" of the cannon ball. I fancy this explanation does not rest on any solid foundation; we have no proof for saying that a cannon ball by its wind, in passing very near to the body, will commit this injury; in fact, if the limb of a person be cut off by a cannon ball, it is certain that the ball must go very near to the other, yet you do not find that other at all injured. There can be no ground then for supposing that these injuries are occasioned by the wind of projectiles. In other cases we find that bones may be broken, although the skin may be uninjured; the state of the skin, therefore, is no proof that considerable violence has not been offered to a part.[1]

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 9139 births and 6227 deaths were registered during the week ending Jan. 18th. The mean annual rate of mortality in these towns, which had been equal to 16·9 and 19·3 per 1000 in the two preceding weeks, further rose to 20·0 in the week under notice. During the first three weeks of the current quarter the death-rate in these towns averaged 18·7 per 1000; the rate during the same period in London did not exceed 18·3. The lowest annual death-rates last week in the 76 towns were 9·1 in East Ham, 10·7 in Walthamstow and in Hornsey, and 11·6 in Tottenham; the rates in the other towns ranged upwards to 29·3 in Oldham, 30·7 in Warrington, 32·2 in Liverpool, and 33·6 in Bootle. The rate in London last week did not exceed 19·8. The 6227 deaths registered in the 76 towns during the week under notice showed a further increase of 209 upon the numbers returned in the two preceding weeks, and included 501 which were referred to the principal epidemic diseases, against 393 and 457 in the two previous weeks; of these, 164 resulted from whooping-cough, 130 from measles, 63 from diphtheria, 59 from diarrhœa, 55 from scarlet fever, 30 from "fever" (principally enteric), but not one from small-pox. The deaths from these epidemic diseases in the 76 towns were equal to an annual rate of 1·6 per 1000, the rate from the same diseases in London being 1·5. No death from any of these epidemic diseases was registered last week in East Ham, Huddersfield, Bournemouth, St. Helens, Hornsey, or in four other smaller towns; the annual death-rates from these diseases averaged upwards in the other towns to 4·1 in South Shields, 5·4 in Merthyr Tydfil, 5·9 in Warrington, and 6·6 in Tynemouth. The fatal cases of whooping-cough, which had been 92 and 127 in the two preceding weeks, further rose to 164 last week; the highest annual death-rates from this disease were 1·9 in Reading and in Aston Manor, 2·7 in South Shields, 3·4 in Merthyr Tydfil, and 3·7 in Warrington. The deaths from measles, however, which had been 103 and 141 in the two previous weeks, declined last week to 130; the highest death-rates from this disease last week were 2·1 in Swansea, 2·3 in Willesden and Rhondda, 3·0 in Wallasey, and 6·6 in Tynemouth. The 63 fatal cases of diphtheria also showed a decline, but included 19 in London, three in Portsmouth, three in Liverpool, 11 in Manchester and Salford, and two in Gateshead. The deaths referred to diarrhœa showed a slight increase and the 55 deaths from scarlet fever also included those returned in recent weeks and included 24 in London, five in Birmingham, five in Liverpool, and two in Middlesbrough. The 30 deaths referred to "fever" also showed a slight increase upon recent weekly numbers; two were returned in Leyton, three in Birmingham, four in Nottingham, nine in Manchester and Salford, and three in Liverpool. The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals, which had declined in the six preceding weeks from 5581 to 4481, had further fallen to 4325 on Jan. 18th. No case of small-pox has recently been admitted to these hospitals. The deaths in London referred to pneumonia and other diseases of the respiratory organs, which had been 333 and 460 in the two previous weeks, further rose to 498 during the week under notice, and exceeded by 112 the corrected average number in the corresponding week of the five years 1903–07. The causes of 57, or 0·9 per cent., of the deaths registered in the 76 towns last week were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Leeds, Bristol, West Ham, Bradford, Nottingham, and in 47 other smaller towns; in London all but one of the 1825 deaths were duly certified. No fewer than 16 of the causes of death were, however, uncertified in Liverpool, six in Birmingham, four in Hull, and three both in Manchester and Burnley.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in eight of the principal Scotch towns, which had been equal to 20·6 and 24·3 per 1000 in the two previous weeks, was again 24·3 in the week ending Jan. 18th, and exceeded by 4·3 the mean rate during the same week in the 76 English towns. Among the eight Scotch towns the death-rates ranged from 16·1 and 17·3 in Aberdeen and Paisley to 28·3 in Leith and 29·3 in Glasgow. The 857 deaths in these eight towns exceeded the number in the previous week by two, and included 158 which were referred to the principal epidemic diseases, against 127 and 143 in the two preceding weeks; of these, 92 resulted from measles, 30 from whooping-cough, 13 from diarrhœa, 12 from "fever," five from diphtheria, five from scarlet fever, and one from small-pox. These 158 deaths were equal to an annual rate of 4·5 per 1000, which exceeded by no less than 2·9 the mean rate last week from the same diseases in the 76 English towns. The fatal cases of measles in the eight Scotch towns, which had been 53, 65, and 84 in the three preceding weeks, further rose to 92 in the week under notice, of which 73 occurred in Glasgow, seven in Greenock, and six in Dundee. The 30 deaths from whooping-cough also showed a considerable increase upon the numbers returned in recent weeks, and included 17 in Glasgow, five in Leith, and four in Edinburgh. The deaths attributed to diarrhœa were, however, somewhat fewer; eight were returned in Glasgow and three in Dundee. Of the 12 deaths referred to "fever" in the eight towns nine were certified as cerebro-spinal fever (including cases in Glasgow and two in Edinburgh), and three as enteric fever, all of which occurred in Glasgow. Of the five fatal cases of scarlet fever three were returned in Glasgow and two in Edinburgh. Diphtheria caused two deaths in Dundee; and the fatal case of small-pox occurred in Leith. The deaths referred to diseases of the respiratory organs in these eight towns, which had been 128 and 205 in the two preceding weeks, declined to 199 in the week under notice, but exceeded by 22 the number from the same training for sanitary inspectors who should undertake the duties of sanitary supervision which are already performed by inspectors of nuisances in Great Britain. It is rightly urged that medical officers of health will not, and cannot be expected to, undertake work of this subordinate character and that the existing establishments of untrained supervisors and overseers are not able to give the health officer the assistance which he has a right to demand. These men form the connecting link between the health officer and the working labourers of low caste coolie class. The training of these sanitary inspectors is a question that will require very careful consideration. The standard required should be that prescribed by the Royal Sanitary Institute for inspectors of nuisances in England and no doubt arrangements can be made to obtain and to train specially selected men and to issue certificates to successful candidates who must be of good physique, satisfactory character, suitable caste and social status, the last qualification enabling them to move freely among all classes of the population with some degree of authority. To attract men of the right stamp it will be necessary to offer good pay and the Government of India thinks that a scale of salaries rising from Rs.50 to Rs.150 (£3 6*s*. 8*d*. to £10 English equivalent) will probably prove suitable in most provinces.

---

[1] Excerpt from "Lectures on Surgery, Medical and Operative, delivered at St. Bartholomew's Hospital by Mr. Lawrence. Lecture XVII."

Finally, the Government of India discusses the question whether the proposed new scheme of medical officers of health and sanitary inspectors should be formed into a regular provincial sanitary service or whether each local authority should be allowed to recruit its own staff independently. The objections urged against the latter course are that a career which is limited to employment by local authorities on uncertain terms and without prospect of pension will not attract candidates of the proper stamp, if, indeed, it attracts any at all, and that the insecurity of tenure will deter men from qualifying for such appointments. The duties of sanitary inspectors of necessity bring them into conflict with members of local authorities, their families and relatives, and if sanitary inspectors are merely servants of local boards they may either neglect their duties in such cases or perform them at the risk of losing their appointments. On the other hand, it may be argued that the creation of a provincial service of sanitary officers will conflict with one of the main principles of local self government and it is urged that in no branch of local administration is local control so necessary as in matters connected with sanitation. The Government of India is convinced that in the case of sanitary officers the certainty of tenure during good conduct must be assured. It will thus be necessary to provide that no medical officer of health or sanitary inspector should be removeable from office without the sanction of the local government in the case of the former, or the sanitary commissioner, or perhaps the sanitary board, in the case of the latter. Regulations somewhat similar to these exist in England and Scotland and are necessary to secure the employment of properly qualified men and to guarantee protection against arbitrary treatment in retaliation for the fearless and efficient performance of duty.

Another part of the administrative machinery touched on by the Government of India in its new scheme is the formation of sanitary boards which would consist of from three to five members, including a senior member of the Civil Service who is in close touch with local administration, the sanitary commissioner and the sanitary engineer as experts, and one or two natives of India, preferably non-officials. Thus direct discussions will be secured between sanitary experts and those who are in a position to appreciate and to represent the attitude and feelings of the general population. The Government of India does not propose to discuss at present the thorny question of sanitation in rural areas. Finally, the question of providing an efficient staff of sanitary engineers has not been overlooked and assurance is given that a separate communication will be made on this matter.

The various suggestions enumerated above are put forward for the careful consideration of local governments and suggestions on some are asked for laying down what specific action they propose to take in order to give effect to the accepted general policy now promulgated of sanitary improvement. It is to be hoped that success will attend this new scheme, the first thorough attempt on the part of the civil authorities in India to place on a sound basis the important question of civil sanitation in its rôle as a prevention of disease. Lieutenant-Colonel J. T. W. Leslie, I.M.S., the present Sanitary Commissioner with the Government of India, is to be congratulated on taking the bull by the horns, and it is to be wished that he will in no way be hampered by financial considerations. Outside the Presidency capitals and a few of the larger cities sanitation may be said to be non-existent, if we except the cantonments of British troops, the latter being mere oases of sanitation in the desert, so to speak, scattered throughout India, and these in most cases are surrounded by mobs of insanitary native bazaars which have sprung up mushroom-like to live on the British soldiers as parasites, fouling his food, air, and environment and infecting him with enteric fever and malaria. With the coöperation of the civil sanitary service as now proposed the sanitary officers of the army will reduce these fell diseases to a minimum and the health efficiency of British troops in India will benefit greatly.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

The Birmingham Housing Reform Association and the Open Spaces Society.

DURING its short but active existence the Birmingham Open Spaces and Playing Fields Society has done excellent work for the city, for it has secured several areas where it was important that breathing space should be acquired, but it has been obvious lately that its work would necessarily overlap with that of the Housing Reform Association and consequently it has been decided to combine the two societies into one under the title of the Birmingham and District Housing Reform and Open Spaces Association. Much work still remains to be done and there can be little doubt that the larger association will work with even greater success than the smaller association attained in the past; therefore the councils of both associations are to be congratulated on the union of their forces.

The Birmingham Ambulance Brigade.

For the third time in succession the Birmingham challenge shield has been won by the Midland Railway division of the Birmingham Corps of the St. John Ambulance Brigade. Councillor Brooks presided at the meeting which was held to celebrate the victory, and in presenting the shield he took occasion to congratulate the whole brigade upon the value and efficiency of its work. The brigade numbers 358 members, and during last year it succoured whilst on public duty 275 cases, and in their private capacities the members have rendered aid to 4398 people. This obviously indicates a large amount of valuable work done at critical moments. 215 members of the brigade have passed the third examination and have received the brigade's medallion, and 46 men have gained the nursing certificate.

Infants in Public-houses.

In addressing a meeting in West Bromwich on social questions Dr. A. E. W. Hazel, M.P., once again drew public attention to the Chief Constable of Birmingham's statement that not a few women take young children into public-houses and some of them have been seen to give beer to infants for the purpose of making them sleepy and quiet. This is one of those glaring disgraces which might be promptly and effectively dealt with by legislation, for surely no sane person would oppose a measure which would make such abominable behaviour illegal, and every right-minded individual will hope, with Dr. Hazel, that the Government will act quickly in a matter which brooks no delay.

The Regulations Regarding Brass Castings.

The proposed regulations drafted with the object of preventing caster's ague are looked upon with great disfavour in Walsall, where it is contended that caster's ague is unknown, the conditions being quite different from those existing in Birmingham. The manufacturers characterise the regulations as arbitrary and unnecessary so far as Walsall is concerned, and they hope that alternative and more reasonable and acceptable regulations will be formulated.

The Water-supply and the Rainfall.

Apparently we may look forward to a dry summer with equanimity, for the rainfall in the Elan Valley during the past year has been quite up to the average, 61·36 inches, and at Whitton and Whitacre, as we had reason to expect, the fall has been above the average, exceeding it at Whitton found guilty and punished as we have stated. In the course of his judgment Mr. Connolly said that he agreed with the contention of the prosecution that the meaning conveyed to the readers of the paper by the articles was that the medical evidence in the case was intentionally and deliberately false, and that it was given in order to screen from punishment a European soldier who had virtually murdered the deceased. The charge was one of perjury, of a criminal offence on a particular occasion, a charge affecting complainant's private as well as his public character. There were, however, several factors that should be taken into consideration in extenuation. These Mr. Connolly proceeded to enumerate at some length, adding his belief that there was no proof that Captain McKecknie had suffered any material damage. The extenuating circumstances, said Mr. Connolly in conclusion, "all call for a lighter penalty than the serious nature of the implication would otherwise demand." It is certainly fortunate for the editor of the *Tribune* that the learned judge was content to listen to the pleadings of mercy.

"Audi alteram partem."

PLEURAL EFFUSION AND ITS TREATMENT.

To the Editor of THE LANCET.

SIR,—I hope the rest of your readers are edified by Dr. Harry Campbell's letter under the above title in your issue of Jan. 11th. I must candidly confess that I am not; however, as I hope to get some educational advancement in physics I continue this controversy. In my first letter I was quite willing to allow an *elastician* of Dr. Harry Campbell's standing to settle the meaning of the term *elasticity*, but on further consideration I find that it will not be confined either etymologically, physically, or in common parlance within the narrow bounds set for it by Dr. Campbell, so I therefore revert to my former position stated in my Bradshaw lecture. With the Greeks an ἐλατὴρ was a driver, a hurler, a charioteer, &c.; ἐλαυνειν to drive, banish, hurl, impel, put to flight, row, lead, carry forward, strike, wound, harass, beat out; ἐλασις the act of riding, driving, a military expedition, march, pursuit, &c.; hence ἐλαστικος and elastic were applied to any implement, such as a catapult, used for hurling missiles by the force of a spring. Possibly David's sling with which he slew Goliath *may* have been of this nature but I shall try a less strenuous method of disposing of my antagonist.

In the "Century Dictionary," which is one of the latest references I have at hand on the subject, I find under the meanings of *elastic*:—

> 2. Having, as a solid body, the power of returning to the form from which it is bent, extended, pressed, pulled, or distorted, as soon as the force applied is removed; having, as a fluid, the property of recovering its former volume after compression. A body is *perfectly elastic* when it has the property of *resisting* a given deformation equally, however that deformation may have been produced, whether slowly or suddenly, &c. All bodies, however, have *different elasticities* at different temperatures, and if the deformation is so sudden as to change the temperature of the body and so alter its *resistance* to deformation, this is not considered as showing it to be imperfectly elastic.

In contradistinction to the foregoing physical definition of elasticity, Dr. Campbell says that when the term is applied to the lungs it signifies "their power of recovering their form after being stretched." This is what the Campbell physicist says, it is a mere property of a certain form of matter by which it has the power of recovering its original form after being stretched, but I prefer the other authority who says that it also signifies a *resistance to stretching or other deformation*.

It is only certain forms of matter which possess this property of *elasticity*, so it is not universal, like gravity. Surely Dr. Campbell will admit that we can measure the force of elasticity even more easily than we can measure the force of gravity. It is not sufficient for him to tell me that it is merely a property of matter, that it is a "power of recovering form after being stretched." The same power that enables elastic matter to recover form after being stretched surely offers an equivalent *resistance* to the process of stretching. This force of *elasticity* can be as easily estimated by the *resistance* as by the *power of recovery*. We can estimate the force of gravity in different latitudes and at different levels above the sea, and it is the force of gravity, rather than any abstract idea of it being a property of matter, which interests us. The same can be said of *elasticity*. How do I know that a collapsed lung is elastic if I do not stretch it? I not only want to know if it be *elastic* but I want to know how perfect is the elasticity. If I stretch the lung to find this out Dr. Campbell tells me: Oh, you are only making the lung *taut*; stop your stretching and you will see the *elasticity*. I reply that I am doing a great deal more: I am finding out the lung's capacity for being stretched and its resistance to stretching; consequently I am finding out the elasticity and the force of the elasticity.

"The elasticity of the lungs does not, as Sir James Barr assumes, rise and fall as these organs expand and contract in respiration, but remains the same. What does rise and fall under these conditions is the pull which the lungs exert on the visceral pleura." If this language means anything it means that the lungs contain a certain amount of elastic tissue in virtue of which they possess the abstract property of elasticity, and as this elastic tissue remains the same whether they are stretched or collapsed their state of tension or tautness has nothing to do with their elasticity. He seems to forget that if they are overstretched as in emphysema or long collapsed as in pleural effusion they lose their elasticity. It is not with any abstract property in the lungs called elasticity but with the manifestation of the force of their elasticity with which we have got to deal. What causes the pull which the lungs exert on the visceral pleura but their elasticity? Dr. Campbell says it is their *tautness*. The lungs might remain stretched when they lost their elasticity, but they would not remain taut without their elasticity. I shall deal with his fibroid tissue later.

Take a perfectly elastic body like air and see how its elasticity does not remain constant, but rises and falls under varying circumstances; it exercises a force equal to that by which it is itself compressed, and with every rise of a degree of temperature there is an increase of elastic force, yet, reasoning from analogy, I suppose, Dr. Campbell would say that the elasticity was a mere property of the air which like that of the lungs "remains the same, but the rise and fall was only in the tautness of the atmosphere."

Now for some more extraordinary reasoning from this writer. He quickly drops the negation called "suction" which he had elevated into a constant force "which sucks blood into the heart. ...... I should not, however, have called attention to Sir James Barr's ambiguous employment of this term—few writers are guiltless of ambiguity—were it not that he assumes, or appears to assume, that the suction, or let us say traction, which the lungs exert on the circumjacent parts is necessarily bound up with their elasticity. Such, as I pointed out in my letter, is not the case. This traction is in direct proportion to the degree to which the lungs are rendered taut—for the more taut the pulmonary tissue the greater is the tug exerted on the visceral pleura—but comparatively non-elastic lungs, such as those seamed with scar-tissue, are capable of being rendered more taut, and thus of exerting *more* traction on circumjacent parts than normal, highly elastic lungs."

This reasoning is that of the academician in his study and not that of the clinician who views facts and reasons therefrom. I shall now proceed to prick the bubble. When a ship is riding at anchor and the strain constant a comparatively non-elastic chain answers admirably, but when the strain is variable, as when a ship is being moored, the hawser is made of highly elastic hemp; if a chain were used there would be constant danger of it snapping or of the ship being damaged by bumps against the quay. The elastic rope offers resistance to being stretched and when the tug of the ship ceases the elasticity gradually pulls the vessel back to its former position. The elastic tension of more or less stretched healthy lungs maintains a constant intrapleural or intrathoracic negative pressure both during quiet inspiration and expiration and thus allows the blood to be driven in at all stages of respiration, but non-elastic fibroid lungs cannot be *taut* both in inspiration and expiration and therefore a constant negative pressure cannot thus be maintained. The idea of the slow shrinkage of fibroid tissue keeping up a constant tautness is too absurd to demand attention; if the cord be *shortened* it may more readily be made taut, but whether short or long there must be an intermittent

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

University of Edinburgh.

THE annual report of the University of Edinburgh for the year 1907 shows that the total number of matriculated students (including 590 women) was 3278, being 79 more than the number for last year, and the highest number reached for 14 years. Of this number 1478 (including 55 women) were enrolled in the Faculty of Medicine, 690, or nearly 47 per cent., belonging to Scotland. Of the remainder 310, or 21 per cent., were from England and Wales; 118 from Ireland; 71 from India; 263, or nearly 18 per cent., from British Colonies; and 26 from foreign countries. These figures show that the proportion of non-Scottish students of medicine is well maintained. The degrees in Arts, Science, and Medicine conferred during 1907 were as follows:—Master of Arts (M.A.), 187 (including 61 women); Bachelor of Science (B.Sc.), 49 (including five women); Doctor of Science (D.Sc.), eight; Bachelor of Medicine and Master of Surgery (M.B., C.M.), two; Bachelor of Medicine and Bachelor of Surgery (M.B., Ch.B.), 197 (including 16 women); Doctor of Medicine (M.D.), 70 (including three women); and Master of Surgery (Ch.M.), two. The General Council of the University now numbers 10,358. The diploma in Tropical Medicine and Hygiene was conferred on five candidates. The total annual value of the University Fellowships, scholarships, bursaries, and prizes now amounts to about £18,520, including in the Faculty of Medicine £3630. In July approval by His Majesty in Council was intimated of an ordinance of the University Court making important changes in regard to the curriculum and periods of examination for graduation in medicine and surgery. The outstanding features are the increased opportunity given to students for taking each of the four professional examinations in separate sections, and the holding of degree examinations in December as well as in the spring and summer. Another change involved in the new ordinance is the opening of the winter session of medicine about a fortnight earlier than at present—i.e., on or near Oct. 1st. Other two ordinances of the University Court—regulations for the degree of Bachelor of Pharmacy and regulations as to bursaries, &c.—have been transmitted to the Privy Council. The only change in the professoriate during the year is that due to the lamented death, which occurred suddenly on Dec. 20th, of Professor Thomas Annandale. Appointed in 1877 as successor to Professor Lister he has long ranked as one of the foremost surgeons and most popular teachers of his time. Dr. W. E. Carnegie Dickson has been appointed lecturer in pathological bacteriology in succession to Dr. J. M. Beattie, now professor of pathology in the University of Sheffield, and Dr. James Arnott, Brigade-Surgeon-Lieutenant-Colonel, I.M.S. (retired), was appointed lecturer in diseases of tropical climates in room of Dr. Andrew Davidson, retired. In the medical building at Teviot-place a new laboratory capable of accommodating 40 students has been provided for the pathology department. Accommodation was again given in August by the University authorities for a scheme of vacation courses in modern languages; also in September for a scheme of post-graduate courses in medicine, held under the joint auspices of the University and the Royal Colleges of Physicians and Surgeons. Both of these schemes proved highly successful.

Lord Lister and the Freedom of Glasgow.

Lord Lister, with Lord Blythswood and Mr. Cameron Corbett, M.P., were enrolled to-day, Tuesday, Jan. 21st, honorary burgesses of the city of Glasgow. The Lord Provost, Sir William Bilsland, having alluded to Lord Lister's connexion with the city as professor of surgery at the University and surgeon to the Royal Infirmary, recalled his lordship's eminent services to mankind as the discoverer of antiseptic surgery. Sir Hector C. Cameron, professor of clinical surgery in the University of Glasgow, one of Lord Lister's former students and his lifelong friend, accepted on Lord Lister's behalf the casket containing the burgess ticket, and read from him a letter recalling his connexion with the University and the city, in the course of which he said: "Having in due time been elected by the managers of the Royal Infirmary as surgeon to that institution, I experienced uniform consideration at their hands when applying to the treatment of wounds the great truth which had been recently revealed by the illustrious Pasteur regarding the nature of fermentative changes in organic substances. That truth, though it seemed to me to shine clear as daylight from Pasteur's writings, was for many years not generally recognised, and thus it was my privilege to witness in my own practice, as the application of the principle became gradually improved, the revelation of pathological truths of fundamental importance and a revolution in practical surgery, and I look upon the years spent in your city as the happiest period in my life. The old infirmary is now giving place to more commodious buildings and, great as must necessarily be the expense in this undertaking, I do not doubt that the proverbial liberality of Glasgow will prove fully equal to the occasion."

Enteric Fever in Glasgow.

A serious outbreak of enteric fever has occurred in the West-end of Glasgow during the latter part of December and the present month. On the occurrence of the first few cases it was found that the patients were all receiving milk from the same dairy. Further investigations revealed the fact that the cart from which the milk was procured received occasional supplies from a farm in the neighbourhood of Glasgow. The medical and sanitary authorities of the city and county thereupon visited the farm where they found a young woman—a member of the household—lying ill in the kitchen bed. She had been ailing from the first week of December and was once visited by a medical man. At the outset she was believed to be suffering from influenza and afterwards the cause of the illness was supposed to be pneumonia. Her symptoms were, however, recognised to be those of enteric fever, her blood giving a positive Widal reaction, and her removal to hospital was at once ordered by the county authorities. Thereafter the farmhouse was thoroughly disinfected and the supply of milk from it was prohibited. Up to the time of writing the number of cases reported in the city from this source is 69, while from the same source cases have been reported in Edinburgh, Uddingston, and Falkirk. There have been several deaths in connexion with the epidemic, one unfortunate case being that of a young man who, while incubating the disease, had gone to Switzerland on holiday and there succumbed to his attack.

Complimentary Dinner to Sir George T. Beatson.

A complimentary dinner was given to Sir George T. Beatson, M.D. Edin., K.C.B., on Jan. 10th, at which there was a large representation of the medical profession and other public men from Glasgow, Edinburgh, and elsewhere who had assembled to do honour to their guest who has recently been invested with the distinction of Knight Commander of the Bath. The Duke of Montrose, who presided, supported the toast of the health of Sir George Beatson, referring to his public-spirited work in connexion with the Scottish National Red Cross Hospital which went to South Africa in 1900 and to his connexion with St. Andrews Ambulance Association and the Western Infirmary of Glasgow. 200 gentlemen were present at the dinner and the proceedings testified throughout to the cordial esteem in which Sir George Beatson is held by his professional colleagues and his fellow-workers.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Tuberculosis Exhibition.

ON Jan. 15th the Tuberculosis Exhibition was opened in Armagh by Sir John Byers, who, in the presence of a crowded meeting in the county court house, gave an address on the formation, objects, and lessons of the exhibition.

Health of Belfast.

The death-rate of Belfast still continues far too high, being for the week ended Jan. 11th 28 per 1000, and 3·8 from the principal zymotic diseases (due to the large number of deaths from measles and whooping-cough). At a meeting of the health committee of the city corporation held on Jan. 16th the superintendent medical officer of health recommended that a steam disinfector should be procured, that one more refuse destructor should be erected, and that the ashbin system should be adopted. A circular has been sent to the butchers of the city by the medical officer of health, urging that meat should be hung at the outside of their shops at such a height as to be out of

The force of elastic recoil of the lungs therefore measures the limit of pressure fall in the pleural sacs which the thoracic expansion can effect. If the lungs have but little elastic recoil and stretch easily very little negative pressure can be produced by the thorax on inspiration; if the coefficient of elasticity be great and the lungs have considerable elastic recoil the inspiratory muscles expanding the thorax have something to pull against and can produce greater negative pressure; if the lungs be comparatively rigid the whole force of the inspiratory muscles can be directly expended on reducing the intrapleural pressure. In this sense Dr. Campbell's contention seems to me physically correct.

On the other hand, there are conditions in which Sir James Barr is correct likewise. For consider the thorax and its respiratory muscles at rest. The lungs remain stretched; they support by their elastic recoil a certain fraction of atmospheric pressure to which the intrapleural space (if space it *may be called*) is *not subjected* in consequence. In that sense, as Sir James Barr states, "there is a slight negative pressure in the pleuræ owing to the elasticity of the lungs." Why all new repair elastic substance in the lungs is laid down in a stretched condition is difficult to see, though the utility of it is obvious. One would have imagined that the elastic tissue would have arranged to be at rest when the thorax was at rest, but it strangely chooses, from birth onwards, never to assume the unstretched condition. There is, therefore, a residual negative pressure for which the pleural sacs are indebted to the elasticity of the lungs and the opposing rigidity of the thorax. For the rest, the active and greater falls, they are indebted to the muscular efforts of the thorax and diaphragm and are distinct losers by the comparatively low elastic recoil of the lungs themselves.

I am, Sir, yours faithfully,
D. W. SAMWAYS.
Mentone, Jan. 16th, 1908.

BRITISH SHIP SURGEONS' ASSOCIATION.

To the Editor of THE LANCET.

SIR,—May we through your valuable journal issue a letter of welcome to all members of the medical profession interested in the formation of the above association? A meeting has been arranged to take place on Monday, Jan. 27th, at 8 P.M., at the Medical Graduates' College and Polyclinic, 22, Chenies-street, Gower-street, London, W., and we hope for a large and representative gathering. The object of such an association has been given in former issues and ship surgeons are almost unanimous as to its need. As some of us from the north are coming at great inconvenience to our practices we do hope that ex-ship surgeons and others now practising in or near the metropolis will do their best to attend.

I am, Sir, yours faithfully,
G. METCALFE SHARPE, Hon. Sec.,
Late Surgeon Cunard and P. and O. Companies.
Jan. 20th, 1908.

LICENTIATES IN MIDWIFERY.

To the Editor of THE LANCET.

SIR,—The annotation upon this subject in the current number of THE LANCET suggests that it would not be inopportune to relate a stage in the history of medical politics in this country, particularly with respect to the education of would-be women medical practitioners. In 1852 the Royal College of Surgeons of England sought and gained in a supplementary charter power to examine "persons" for a diploma—Licentiate in Midwifery of the Royal College of Surgeons of England, commonly abbreviated to "L.M." It is said that the inclusive word "persons" in Clause 17 of the new charter was introduced deliberately. Under Schedule A (4) of the Medical Act, 1858, such persons might be "registered" with this single qualification. It was, however, urged by some that the "L.M." diploma was *only* to be issued to men who were already otherwise qualified. The Medical Act, 1875, sec. 2, did not vary the position. This diploma was suppressed in 1876. In 1872 the King's and Queen's Colleges (now the Royal College) of Physicians in Ireland made their midwifery licence registrable; in 1874 they granted diplomas to midwives. It was not, of course, until the Medical Act, 1886, sec. 2, became law that a triple qualification in medicine, surgery, and midwifery was essential prior to the registration of the name of a would-be medical practitioner.

The Female Medical Society (1862-72) was founded "to provide educated women with proper facilities for learning the theory and practice of midwifery and the accessory branches of medical science." The Ladies' Obstetrical College (Great Portland-street) was founded in 1873. In 1875 Miss Sophia Jex-Blake, Miss Edith Pechey, and Mrs. Thorne, having been informed of an opinion of counsel given to the College of Surgeons as to the scope of Clause 17 of their enlarged charter, and having fulfilled all precedent requirements, claimed to be "persons" who must be examined by the Royal College of Surgeons for the licence in midwifery. In this way they hoped to secure admission to the Medical Register. The midwifery board of examiners of the College, led by the late Dr. Robert Barnes, resigned in protest, thus postponing in January, 1876, the examination *sine die.* It has never since been conducted. The Obstetrical Society of London concurred with this practical protest. The late Dr. Robert Barnes, writing to me in October, 1906, said with respect to this incident: "I may say that I rescued the College and the profession from the disgrace of issuing a barren midwifery licence."

I am, Sir, yours faithfully,
Adelphi-terrace, W.C., Jan. 13th, 1908. STANLEY B. ATKINSON.

A CASE OF "DIPHTHERIA OF THE SKIN."

To the Editor of THE LANCET.

SIR,—Dr. J. G. Hare is to be congratulated in clearing up the nature of Dr. Alan B. Slater's remarkable case of cutaneous diphtheria as reported in THE LANCET of Jan. 4th. The case raises some interesting pathological issues, particularly in regard to the underlying cause of a diphtherial infection so extensive. It is, however, perhaps unnecessary to infer such an unusual course of events as that suggested by Dr. Slater in his ingenious explanation. Diphtheria bacilli do not spread far and wide *viâ* the superficial lymphatics, but they are conveyed at times from one abraded surface to another by auto-inoculation. Moreover, while neuritis is an ordinary and specific feature of diphtheria, herpes of the neuritic type is rare in that disease—is, in fact, commoner in other infections, notably scarlet fever, which present the rash as a pure complication.

The peculiar characteristics of the case being the widespread distribution of the lesions and their long duration, it seems to me that if auto-inoculation be accepted an explanation based on established pathological facts is forthcoming. It is well known that nurses with slight abrasions of the fingers may, when working in diphtheria wards, develop a localised diphtherial infection and that a permanent cure may not be obtained for weeks or even months if antitoxin is not given. It may happen that more than one finger is infected, and there seems to be no reason why this modified form of diphtherial lesion should be restricted in distribution where the inoculable points are multiple. Given, then, that the original conjunctivitis and vulvitis were wholly or partly septic in nature, it might well be that the patient developed a spreading septic rash such as is often seen under such conditions in children. The cutaneous abrasions would offer points of inoculation, and the diphtheria bacillus, established anywhere from mixed infection of the eye or vulva or from an outside source, would be readily carried in the discharges from one area to another.

Now that Dr. Hare has proved bacteriologically the nature of one case, there is the interesting possibility that other obstinate skin affections of a similar type may also turn out to be diphtherial.

I am, Sir, yours faithfully,
JOHN BIERNACKI.
Plaistow Hospital, London, E., Jan. 12th, 1908.

ACUTE PULMONARY ŒDEMA.

To the Editor of THE LANCET.

SIR,—With reference to the interest lately awakened by the able dissertation upon acute pulmonary œdema by Dr. Leonard Williams in THE LANCET of Dec. 7th, 1907, may I be permitted to add my humble testimony of what I consider to be a most remarkable and typical example of the condition. At 10 P.M. last night I was summoned to see a man who, I was told, had been taken suddenly and severely ill. I immediately set out and arrived on the scene within five minutes of the summons to find the patient dead.

The history was as follows. The patient, a man, aged 48 years, had been at his work all day apparently in the best of violence a patient in the same asylum having surreptitiously got hold of a copper-lid from the refectory, inflicted a murderous blow with it on another patient's skull, on whom the operation of trephining had to be performed, fortunately in time to save his life. Again the public press, in anticipation of the results of judicial inquiry, is calling loudly for a more effective *personnel*, in numbers as well as in aptitude, if only to bring the "madhouse administration" of Italy up to something like the standard reached and maintained north of the Alps. Dr. Giovanni Mingazzini, professor of neuropathology and psychiatry in the University and director of the Manicomio of Rome, has just intervened in the discussion of this topic and with an authority which few of his Italian contemporaries can claim. Admitting the deplorable incidents all too common in the asylums of Italy he concedes what has been pointed out above—the inadequacy of the *personnel* to the surveillance of the patients. The Roman Manicomio, in particular, is overcrowded—its inmates being far beyond the control of the official attendance, and this he attributes to the practice of the law courts in relegating to the purely medical asylums those criminals who, undoubtedly insane, are better fitted for such special establishments as that of Montelupo in Tuscany than for those asylums where patients are admitted for treatment with a reasonable hope of recovery. As to the clamour raised in some quarters for more stringent restraint, he opposes that system as at once unscientific and ineffective —quoting with approval the dictum of an Italian alienist: "It is not so much the mental disease that instigates the patient to deeds of violence; it is rather the coercion which, depriving him of the power of moving, determines in him a reaction abnormal and antagonistic, exploding in aggression." Paying a high tribute to Dr. Conolly of Hanwell who, nearly 50 years ago, put the non-restraint system in practice, he draws a pathetic picture of the risks incurred by asylum directors in Italy who, fully convinced of the efficacy of non-restraint, have yet to contend with the disadvantages due to the defective *personnel*—to the lack of that sufficiency of attendants which alone makes non-restraint practicable. Dr. Mingazzini's letter, written with ratiocinative force and literary *brio*, ought to have a salutary effect on "asylum reform"—one of Italy's most urgent desiderata.

The Italian "State Quinine" in Greece.

The Greek legislature has just approved on the third reading of a Bill for the introduction of "State quinine" of the type of that existing throughout Italy by the Law of 1900. The Government at Athens has put itself in communication with that of Rome for the supply of the preparation in question as manufactured in the Farmacia Centrale of Turin. Specimens of this product had, it seems, been obtained by the Greek Red Cross Society for purposes of experiment, with the result that the Government at Athens has not only adopted the Italian law as to its use but is about to employ the identical product itself. This imparting of "good offices" by Italy to Greece is of gratifying augury (so says the leading Roman journal) for the future of the two ancient civilisations.

Science and Surgery at Bologna.

The "Mater Universitatum" on the 8th inst. lost, within a few hours of each other, two of her brightest ornaments. One is Professor Domenico Peruzzi, domiciled at Lugo, the distinguished surgeon, *ætatis* 89, known throughout Italy as the first operator to perform laparotomy with a successful result. A colleague of his at Pisa had indeed the priority in the operation but the patient did not recover. The other "scienziato," also an octogenarian, is Professor Paolo Ruffini who, after a brilliant career in the Bologna school, became professor of the higher mathematics at Modena. He had also been a combatant in his country's cause and for his share in the battle at Governolo in 1848 had been exiled by the then ruler of the duchy.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

The Influence of General Anæsthetics upon the Blood.

AT a recent meeting of the Vienna Gesellschaft der Aerzte Dr. Reicher communicated the results of a series of experiments which he had made with a view to ascertain the chemical influence of certain anæsthetics (ether, chloroform, and A.C.E. mixture) upon the blood. The experiments were made on dogs which after having been kept under observation for several days were anæsthetised for 90 minutes. Whilst the animals were still under the influence of the anæsthetic blood was withdrawn from the femoral artery and the amount of lecithin, cholesterin, and fat contained in it was ascertained by extraction with a mixture of alcohol and ether; the amount of ammonia, nitrogen, and acetone was also estimated. The latter substance was, moreover, sought for in the expired air. A considerable increase in the amount of fat (up to three times the normal quantity) was found in the blood and acetone was also present in a higher degree, especially in the expired air and in the urine. Dr. Reicher believed that the fat in the blood was sent thereto from the normal deposits of fat in order to neutralise the anæsthetic and thus to spare the red cells. If this fat was not sufficient then the lipoid bodies from the central nervous system were sent into the blood, as was proved by the presence of lecithin and cholesterin. Only a few anæsthetic substances attacked the erythrocytes directly. The alkalescence of the blood was lowered, because the red cells when disintegrated formed acid substances. In alcoholic intoxication oxybutyric acid and acetic acid were demonstrated in the urine. The acetone was derived from the disintegration of fat and albuminoid bodies. Acetonuria and lipæmia were closely related to each other, so that diabetic persons might easily show the latter condition, and general anæsthesia was therefore a dangerous procedure with them. Dr. Reicher commented on the similarity of general anæsthesia and diabetic coma.

Cancer of the Stomach Consequent on Swallowing Caustic Potash.

At a recent meeting of the Vienna Medical Society Professor Ghon showed some of the viscera of a boy, 13 years of age, who died not long ago. In December, 1906, he swallowed a quantity of a weak solution of caustic potash, whereupon violent vomiting followed. In course of time he showed symptoms of stenosis of the œsophagus which necessitated protracted use of bougies, and jejunostomy had ultimately to be performed on account of a stenosis of the pylorus. Death was due to intercurrent broncho-pneumonia. The necropsy revealed stenosing erosion of the pylorus, two external erosions of the transverse colon which also had caused secondary stenosis by contraction, stenosis of one ureter, and chronic inflammatory changes of the peritoneum originating from the stomach. On the lesser curvature there was a perforation in the midst of a tumour-like mass which on histological examination proved to be carcinoma. This case is interesting on account of the age of the patient, for he is one of the youngest persons of whom there is a record as suffering from carcinoma, if ovarian and uterine neoplasms are not taken into consideration. Another point of interest in the case is the connexion between chronic irritation and malignant growth.

A Small Outbreak of Enteric Fever.

During the last three weeks a number of cases of enteric fever have been brought to the notice of the sanitary authorities and this gave rise to some uneasiness, for the Vienna water-supply is so pure that no epidemics of this kind have occurred for about 25 years. It was soon possible, however, to trace the source of infection to contaminated milk and the outbreak was quickly stopped. Whilst every care is taken to insure the supply of pure fresh milk to the city a certain dealer in a village where enteric fever existed unfortunately added infected water to the milk. The milk-supply of Vienna is to a great extent centralised and the milk is subjected to pasteurisation in most of the dairies, but by some misadventure the heating process was interrupted on these occasions before the milk was sterilised, with the result that 35 cases of enteric fever appeared in a certain district and two cases have ended fatally.

Radio-active Baths in Bohemia.

The Government has formed a bathing establishment at Joachimsthal, a mining district in northern Bohemia (from which the thaler, and consequently the dollar, derived its name), where pitchblende containing radium is found, and this establishment will be supplied with radio-active water directly from the mines. Notwithstanding the receipt of many offers from Karlsbad, Marienbad, and private persons the Government declined to let the control of the water pass out of its hands. The establishment will be under the superintendence of a medical man and as the water has a very high index of radio-activity its effect will have to be watched and studied very glad to be assured that Dr. Bashford dissociates himself from such a conclusion. I find, however, that four months after Dr. Bashford's and Dr. Murray's paper, which contained the above quotation, was read Professor Farmer at a meeting of the Pathological Society of London held on May 17th, 1904, and reported in the *British Medical Journal* of May 21st, 1904, p. 1196, observed "that although the authors" (Messrs. Farmer, Moore, and Walker) "had been credited with the view that they had arrived at an explanation of the phenomena of carcinoma they disclaimed this; the relation between heterotype mitosis and the life-history of carcinoma they did not profess to explain."

I am, Sir, yours faithfully,

Driffield, E. Yorks, Jan. 18th, 1908. A. T. BRAND.

DEATH UNDER AN ANÆSTHETIC.

To the Editor of THE LANCET.

SIR,—In THE LANCET of Dec. 14th, 1907, p. 1714, is a report of an inquest upon a case of death under an anæsthetic upon which I gave evidence as to the post-mortem appearances. Amongst other remarks I am reported to have said that I considered coughing might have acted as a "shock" to the heart. If I used the word "shock" it must have been thoughtlessly and in ignorance of the fact that the word might appear in print. My opinion is that the deep inspiration which follows a forcible expiration may affect the heart and that the heart—judging from the clinical evidence—was thus affected in this particular case.

It has never seemed to me that adhesions of the pleura or pericardium are important factors in the production of the so-called "pulsus paradoxus." Yet in this case it may be of interest to mention that firm adhesions obliterated both the right and the left pleural cavities. The consequent inability of the lungs to advance over the heart during inspiration may have aided to produce a distension of the heart which, weakened by the anæsthetic and defective aeration of the blood—owing to the presence of thick muco-pus in the bronchial tubes—proved fatal.

I am, Sir, yours faithfully,

Jan. 23rd, 1908. THEODORE FISHER.

THE PRESENT PROSPECTS OF THE MEDICAL PROFESSION.

To the Editor of THE LANCET.

SIR,—Every thinking person must feel that the present condition of affairs requires serious consideration. Have we passed the zenith of our fame and power? Has rapid progress brought with it the seeds of decay and impotence? If it is true, as has been asserted, that the average income of a medical man is under £250 a year, the number of parents and guardians anxious to send their children and wards to the profession is certain to decrease. Young men are seldom tempted to a medical career by the fervid enthusiasm which determines to an ecclesiastical vocation. Medicine shares none of the high prizes of the law. The most that the majority of its members can hope for is a moderate competence with a slender provision for old age. It is probable that many causes acting concurrently have combined to bring about the present state of affairs and I propose to comment briefly on some of them.

The agricultural population shows an increasing tendency to flock to the towns and, as Canon Jessop has remarked, the old village life has all faded away. Even in districts in which corn and other crops are still cultivated extensively improved agricultural implements have diminished the demand for labour and the railways have brought all except the remotest districts into touch with towns where patients can consult some medical man renowned for special knowledge of their ailments. It is therefore clear that large districts will require fewer medical men in future and will afford poorer remuneration. Here we are face to face with causes entirely non-medical and most unlikely to change, except for the worse.

The inevitable growth and development of specialism which increased knowledge has produced have aided, no doubt, in the reduction of the income of the general practitioner, but other causes are, in my opinion, as powerful, if not more so, in London and other very large towns. One of these is the abuse of medical charities, for it is a matter of common knowledge that thousands of persons well able to pay an ordinary fee prefer to present themselves at the out-patient department of some great hospital. Another difficulty with which we have to contend is the fact that quackery displays everywhere her various illusions to cheat the hopes and prey on the weaknesses of mankind, while faith-healing, crystal gazing, and palmistry are rampant. We know from the sixth satire of Juvenal that pretenders of a like kind existed in ancient Rome:—

> "Frontemque manumque
> Praebebit vati crebrum poppysma roganti."

It must not be forgotten that as a profession we are placed at a great disadvantage as compared with other callings, because the sciences on which our art is based are to a considerable extent occult sciences to even the majority of the most cultivated of the laity. The proposition that with the advance of hygiene disease will fade away is in all probability no more than a beautiful dream, "born of hope and destined to die of experience." Preventive medicine may indeed arrest the progress of some epidemics; though, as in the matter of the vaccination laws, it seems doubtful whether with the advancing wave of democratic ideas there will not be an increased disinclination to submit to the restraints which the medical profession may recommend for the physical welfare of the community.

In the lives of professions, as in the lives of states, of senates, of individuals, there are periods for pause and thought. The present time seems to me a desirable one in the life of medicine. Never at any period, I believe, have the heads of medicine and surgery been more faithful workers, more true to nature, or have conferred larger benefits on the human race. To their wisdom and guidance I trust that the difficulties of the present may be removed and that in the future the triumphs of the past may become even greater and brighter than before.

I am, Sir, yours faithfully,

Jan. 20th, 1908. INSPECTOR-GENERAL.

CIVIL SANITARY REFORM IN INDIA.

(FROM A SPECIAL CORRESPONDENT.)

A MOST important letter has been addressed by the Government of India to all local governments and administrations for their opinion on the subject of sanitary reforms in civil areas. In the past practically no attention to this important subject has been paid, if we except the Presidency capitals and a few of the larger cities. The letter now addressed indicates the nature and direction of the advance which in the view of the Government of India (under the advice of the new sanitary commissioner who was appointed in 1904) should now be made towards the reorganisation of the sanitary department. The Government of India now suggests that the posts of deputy sanitary commissioners should not exclusively be reserved for officers of the Indian Medical Services but should be *thrown open* to all medical officers of health who must in all cases possess the D.P.H. diploma. The present inadequacy of the staff of medical officers of health is pointed out and it is suggested that the proposed new sanitary service will offer a suitable and congenial career for educated Indians who have been trained in Europe, the latter essential being absolutely necessary. In towns with a population between 20,000 and 100,000, however, it will be necessary to accept a lower standard of scientific attainments, and such posts may be suitably offered to educated natives of the assistant surgeon class. Here I may remark lies the greatest pitfall of the scheme, as this class of medical practitioners in India are mainly recruited from the Brahmin caste, which sect according to caste prejudices becomes defiled by contact with latrines and the like, so it may be assumed that inspection of such an important source of public health pollution will not be as rigidly performed as it would be by European medical officers of health. The Government of India also suggests that in future medical officers of health from the Indian Medical Service will not be appointed deputy sanitary commissioners unless they have more than seven years' service. Medical officers of health will not be allowed to undertake private practice and their salaries will therefore have to be fixed on a more liberal scale than would otherwise be necessary.

The supervision of the conservancy establishment in municipal towns is in urgent need of reform and it is imperative that steps should be taken to provide efficient whom all local officers should obtain their supplies according to requirements before Nov. 1st in each year. To Government servants lancets will be issued free of charge, but cost price will be charged to municipalities, private firms, and individuals. A reserve stock of permanganate of potassium crystals will be kept at all hospitals and dispensaries for distribution to those who have lancets when the supply of permanganate contained in each lancet is exhausted.

Rabies in Jackals.

Owing to the prevalence of rabies in Simla the health officer attached to the Simla municipal council has started a campaign against jackals, large numbers of which exist in the vicinity of India's summer capital. A special man has been engaged to exterminate these animals by poison and also by shooting them. Bites caused by rabid jackals are always of much greater severity and graver prognosis than dog-bites.

The Serum Therapy of Plague.

Khan Bahadur N. H. Choksy, M.B., special plague officer, Bombay, has just published a valuable pamphlet recording recent observations on the serum-therapy of plague in India. It has been contended by some people that the serum treatment of plague cases is ineffectual, if not altogether useless, and that the results are entirely disappointing. Dr. Choksy contends that, having regard to the unfavourable conditions that are almost unavoidable in the treatment of a disease like plague, the wonder is that serum treatment has given such comparatively good results. He supports this assertion by an elaborate discussion of over 1600 cases treated at Bombay, Poona, Indore, Calcutta, and Karachi. The average mortality in plague cases in Bombay is about 89 per cent.; in cases treated with serum the incidence of mortality varied from 33·3 among a small number of Europeans, to 40 per cent. among Parsees, 44·3 per cent. among Mahomedans, and 55 per cent. among Hindus. Dr. Choksy contends that "the serum treatment is the only method of saving a larger proportion of lives in a certain class of patients." At the same time it cannot favourably influence all types of plague; in hospital practice where more than half the cases are of the septicæmic type on admission, and consequently not amenable to any specific treatment, it must be of comparatively little value. The essence of successful serum treatment is that it should be commenced at an early stage of the disease. This is rarely possible with hospital patients, most of whom have been suffering several days before admission. But in the case of private patients who call in a medical man at once the results are undoubtedly favourable. Among 468 private patients the case mortality was only 39·9 per cent., while among 613 specially selected hospital patients it was 57 per cent. Again, among first-day patients the case mortality was 30·3, among second-day patients 52·6, and among third-day patients 63 per cent. These figures show, as Dr. Choksy contends, favourable results, and if patients could be taught to apply for treatment as soon as they were attacked the results would be still more satisfactory.

The Chinsura Cholera Cases.

Three tragic deaths which occurred recently from cholera have been the subject of a special investigation by Major Clarkson, I.M.S., sanitary commissioner, who traced the transmission of the cholera germ to the jharans (cloths used for cleaning dinner plates) of one of the servants of the house. Mr. Bernard, Commissioner, Mrs. Bernard (his wife), and a Miss White, a visitor, were the victims; several others who partook of food with them were also attacked but recovered. The jharans were infected by being washed in a portion of a river where a cholera corpse of a native had been lying, the disease being transmitted to the dinner plates by the infected jharans.

Jan. 4th.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Huethe, formerly surgeon-general of the German Navy, at the age of 74 years, who had been living in retirement since 1894. He was for some time a professor in the Naval Military Academy at Kiel. His death took place at Capri.—Dr. Donner, formerly professor of physiology in the Tours Medical School.—Dr. H. P. Loomis, professor of therapeutics and materia medica in Cornell University.—[illegible] ments [illegible] chemical influence of certain anæsthetics (ether, chlorofo

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At the first professional examination held on Jan. 7th, 8th, 9th, and 10th, the following gentlemen were approved in the subjects indicated:—

Chemistry and Physics.—Gilbert Bailey, Manchester University; Basil Fraser Beatson, Leys School, Cambridge; William Hackett Broughton, Manchester University; Frederick William Campbell, University College, Cardiff; Rowland Burnell Campion, Guy's Hospital; Nai Cheune, London Hospital; Henry Dyer Scott Close, St. Thomas's Hospital; Edward Percy Drabble, London Hospital; Charles Alexander Robertson Gatley, Guy's Hospital; John Llewellyn David Lewis, Guy's Hospital; Victor Alfred Luna, Guy's Hospital; Leonard Robert Pickett, Tonbridge School; Henry Charles Rigg, Charing Cross Hospital; William Andrew Thompson, Guy's Hospital; Claude de Boudry Thomson, Middlesex Hospital; Claude William Treherne, St. Thomas's Hospital; Arnold Viney, Oundle School; and Sydney Arthur Wilkinson.

Chemistry.—Ahmed Abdel-Al, Guy's Hospital; Frank Cunninghame Cowton, Alexander Rentoul Esler, and Maberly Squire Esler, St. Thomas's Hospital; Hassell Dyer Field, Battersea Polytechnic; Meredydd Foulkes, St. Thomas's Hospital; Francis Henry Guppy, St. Bartholomew's Hospital; Frank Mainwaring Hughes, Gerald Noel Martin, and David Scott, London Hospital; Ivan Lindley Waddell, St. Bartholomew's Hospital; and William Neville Pennant Williams, Liverpool University.

Physics.—Allan Stanley Coalbank, St. Bartholomew's Hospital; William Trevor Flooks, University College, Cardiff; Owen Gwatkin, Manchester University; William Fidler Mason, Leeds University; Eugene Andrew Joseph Murphy, King's College; Edmund Unlacke Russell, King's College; Charles Pearse Crodacott Sargent, St. Bartholomew's Hospital; and Henry Stanley Young, Birkbeck College.

Biology.—Ramrao Belcrushma Agaskar and George Aspinall-Stivala, St. Bartholomew's Hospital; Gilbert Bailey, Manchester University; William Somerset Birch, King's College; Herbert Chorley, Liverpool University; Arthur George Bisset Fenwick, St. Thomas's Hospital; Geoffrey Garland, Leeds University; Charles Alexander Robertson Gatley, Guy's Hospital; William Edward Hallinan, Charing Cross Hospital; Leslie Price Harris, Guy's Hospital; John Rollo Hayman, Middlesex Hospital; George Basil Henley Jones, Guy's Hospital; Edmund Thomas Howard Lea, Westminster Hospital; David Lewis, London Hospital; Victor Alfred Luna, Guy's Hospital; Alexander Macrae, London Hospital; Reginald Victor Martin, St. Mary's Hospital; Arthur Geoffrey Morris, University College, Bristol; Eugene Andrew Joseph Murphy, King's College Hospital; Frank Andrew Miller Nelson, London Hospital; Jorabhai Bhaibabhai Patel, Bombay University; Montague Pern and George Brentnall Pritchard, Guy's Hospital; Walter Alexander Reynolds, St. Mary's Hospital; Henry Charles Rigg, Charing Cross Hospital; Charles Pearse Crodacott Sargent, St Bartholomew's Hospital; Jelal Moochool Shah, Bombay University and St. Bartholomew's Hospital; Cuthbert Shaw-Crisp, St. Mary's Hospital; William Andrew Thompson, Guy's Hospital; Chunilal Bhimbhai Vakil, St. Bartholomew's Hospital; William Cuthbert Whitworth, Guy's Hospital; William Neville Pennant Williams, Liverpool University; and William Wörger, University College, Bristol.

At the Preliminary Science Examination for the Licence in Dental Surgery held this month the following gentlemen were approved in the subjects indicated:—

Chemistry and Physics.—Robert Reginald Adams, Guy's Hospital Edwin Randolph Bailey and Henry Leonard Bailey, Polytechnic Institute; Stanley Maddox Gardner, Technical Institute, Wandsworth; Robert John Harley-Mason, Birkbeck College; Guy William Enstone Holloway, Polytechnic Institute; Sidney William Ingram, Guy's Hospital; William Howard Keay, Walsall Technical Institute; Sidney Saxton, University College, Bristol; Herbert Thornton, Guy's Hospital; and Thomas Reginald Trounce, Birkbeck and City of London Colleges.

Chemistry.—Ernest Walter Bacon, Alleyn's School; Arthur Raymond Goddard, University College, Nottingham; Cyril Arthur Pollard, Birkbeck College; James Stacey Robinson, Walsall Technical Institute; George Wesley Royle, Modern School, Bedford; and James Bennett Sharp, Charing Cross Hospital.

Physics.—Charles Repton Faulkner, Birmingham University; Thomas Leonard Fiddick, Guy's Hospital; Roy William List, Charing Cross Hospital; William Macqueen Potter, Birkbeck College; and Frank Percival Sturdee, Northern Polytechnic Institute and Birkbeck College.

At the quarterly examination in Practical Pharmacy held on Jan. 16th the following gentlemen were approved:—

Burgess Barnett, St. Bartholomew's Hospital; Charles Thornton Vere Benson, B.A. Cantab., Cambridge University and St. Thomas's Hospital; John William Bowen, private study; Frederick William Campbell, University College, Cardiff; Arthur Henry Howard Catt, Charing Cross Hospital; Nai Cheune, London Hospital; Thomas Bonnor Davies, St. Bartholomew's Hospital; Maurice Dwyer, Leeds University; Harold Delf Gillies, Cambridge University and St. Bartholomew's Hospital; Arthur Oliver Gray, King's College Hospital; Claud Anthony Holburn, Sheffield University; George Barrowclough Horrocks, Victoria University, Manchester; Gilbert Percy Humphry, St. George's Hospital; Colin Mackenzie, B.A. Cantab., Cambridge University and Middlesex Hospital; Dalton Mallam, London Hospital; Samuel Marle, University College, Bristol; Guy Harvey Mead, St. Thomas's Hospital; George Hugh Bertram Charles Noble O'Reilly, London Hospital; Arthur Hardwicke Platt, Piercy, University College, Bristol;

by 3·27 inches and at Whitacre by 2·76 inches. To a certain extent this satisfactory result on the gathering grounds whence our water-supply is derived may be considered as a compensation for the past dreary summer.

Medical Inspection of Schools in Worcestershire.

If the conditions in Worcestershire are to be taken as an indication of the terms on which the medical officers engaged for the inspection of school children will have to work and of the work which they will have to do, then it may be admitted that the pay will not be over-generous and the work if it is well done will be heavy. The sanitary subcommittee appointed to report upon the best method of carrying out the administrative provisions of the Education Act of 1907 in Worcestershire recommended that the education county, which contains 251 public elementary schools, should be divided into three districts, in the largest of which the school children would average 18,471 and in the smallest 12,164. The subcommittee was of the opinion that a medical inspector should be appointed for each district and that the work should be supervised by the county medical officer. It proposed that the county medical officer's salary should be increased by £100 per annum, that one of the inspectors should receive £500 per annum, rising to £600, and the other two £350, rising to £400, and it suggested that one of the medical inspectors should be a woman. The report was subjected to a considerable amount of criticism and opposition and it was eventually decided that the education committee should recommend the council to appoint three medical inspectors who should commence with salaries of £250, rising to £300. This does not seem too much for the work to be done, yet the cost to the county will be very considerable and there seems every probability that the scheme will have to be enlarged if satisfactory results of any substantial character are to be looked for. Apparently, according to the reports, the scheme makes no provision for the fees of specialists, yet numerous cases must be met with in which specialists' opinion will be invaluable and will no doubt have to be obtained. It will be well to expect that the early estimates of cost for all schemes of this nature will prove insufficient and to make up our minds to face considerably increased taxation, whilst it is to be hoped that the results may give a satisfactory return for the expenditure. Expression was given to fear of increasing expenditure when the report was presented to the council. Objection was made to the appointment of whole-time inspectors and the report was referred back to the committee for further consideration. What the committee will do is not clear, for no reasonable person can expect that the work required by the Act can be properly done by district medical officers of health who are already burdened with duties.

Jan. 21st.

WALES AND WESTERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENTS.)

Carmarthenshire Water-supply.

FOLLOWING the example of the steam coal areas of Glamorgan it is proposed in the anthracite district of Carmarthen to go away from the coal district for a supply of water. This eventuality was foreshadowed in 1904 when the Local Government Board refused to sanction a scheme of the Llanelly rural district council for the supply of Burry Port, where there is a population of about 4500, with water obtained from the coal measures. The local authorities cannot be accused of being precipitate in the action now proposed to be taken, for as long ago as 1901 the Carmarthen county council decided to make a representation to the Local Government Board in accordance with the provisions of Section 299 of the Public Health Act, 1875, to the effect that the Llanelly rural district council had made default in enforcing the provisions of that Act.[1] In the coming session of Parliament there will be promoted two Bills, each concerned with securing a supply of water for the district named. In both proposals the supply is to be obtained from the head waters of the river Loughor. The larger undertaking, which is estimated to cost £95,000, is that of the Burry Port urban district council jointly with the Llanelly rural district council. The second scheme, the cost of which is estimated at £32,000, is being put forward by the Ammanford urban district council which has undertaken to supply the adjoining rural district of Llandilo.

Cardiff Water-supply.

The inhabitants of Cardiff are supplied with water from the old red sandstone of the Breconshire Beacons, and in spite of the increase in the size of the town sufficient provision has been made to insure an ample amount both for domestic and municipal purposes. During last year the average daily consumption per head was 27 gallons, of which 11 gallons were for trade and municipal requirements. The revenue from the undertaking is not yet sufficient to meet all the charges and a rate in aid has to be levied. It is anticipated that in a few years the latter will not be necessary. The sum of £280 is paid yearly for the water supplied to the public baths and it has been suggested that when the water in the service reservoirs is running to waste a sufficiently increased amount of water should be supplied to the baths to enable them to be emptied much more frequently than once a week as is the case at present. The proposal is one which should meet with favourable consideration.

Cardiff and the Notification of Births Act.

Notwithstanding the fact that the health committee of the Cardiff corporation recommended the city council not to adopt the Notification of Births Act, the council after some discussion decided that the Act should be adopted. In a special report upon the incidence of infantile mortality in Cardiff which was made by the medical officer of health in January, 1907, Dr. E. Walford urged the employment of qualified health visitors or women inspectors to visit the houses of the poor in which infants are born. Already one such inspector was attached to the health department but her work was hampered owing to the length of time which usually elapsed between the birth and the time of registration. A scheme of voluntary notification of births by the midwives in the town was proposed by Dr. Walford and he suggested a fee of 1*s.* being paid to each midwife who notified a birth within 48 hours of its occurrence. The action of the corporation in adopting the Notification Act will necessitate the appointment of another woman inspector, and that there is sufficient work ready to her hand is evident from the high rate of infantile mortality in some parts of the city. In the third quarter of the four years 1903–06 the rate in the whole of Cardiff was 142 per 1000 births, but in one part of the town it was 178 per 1000, and in another part as high as 189 per 1000.

Proposed Cottage Hospital for Pontypridd.

The populous valleys which spread out almost fan-like from Pontypridd are very ill-provided with hospital accommodation. In the Rhondda valleys there is only one such institution situated at Porth and with accommodation for 13 patients. In the Aberdare valley there are small hospitals at Mountain Ash and at Aberdare, while in the Taff valley there is at Merthyr a well-equipped hospital of 45 beds. Pontypridd has a population approaching 40,000 persons and is the centre of an extensive coal mining district so that the need of a general hospital is apparent. At a public meeting held in the town on Jan. 15th it was decided that the urban district council should be asked to build a small accident hospital and to support it out of the general rates of the town. At Barry the rates have been applied in support of a similar institution for many years.

Medical Officer of Health for Monmouthshire.

At the next meeting of the Monmouthshire county council a proposal will be made to appoint a medical officer of health part of whose duties will be the supervision of the medical examination of the children attending the public elementary schools in the county. The suggested salary is £600 per annum, together with travelling and other expenses. The area of the administrative county is 345,000 acres. About three-fourths of the county is of a rural character and the remainder includes the thickly populated districts of the eastern and western valleys where coal mining operations are extensively carried on. The population of the administrative county is about 250,000 and there is every probability that the number of persons employed in the collieries of the district will increase in the future.

Traitement de la Tuberculose par la Paratoxine. Basé sur l'Action antitoxique du Foie. *Par E. Gérard, Professeur de Pharmacie* et de Pharmacologie à l'Université de Lille, et G. Lemoine, Professeur de Clinique Médicale à l'Université de Lille. Price Fr.1.50.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

ANDERSON, C. M., M.D. Edin., has been appointed Clinical Assistant to the Samaritan Free Hospital for Women.

BARBER, B. A., M.D., M.S.R.U.I., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Dronfield District of the county of Derby.

BURY, REGINALD FREDERICK, M.R.C.S., L.R.C.P. Lond., has been appointed Honorary Surgeon to the Warneford Hospital, Leamington Spa.

CULROSS, JAMES, M.B., C.M. Glasg., has been appointed to the Honorary Medical Staff of the Newton Abbot Hospital.

GLOVER, J. A., M.D. Cantab., D.P.H., has been appointed Deputy Medical Officer of Health to the Islington Borough Council.

GRIMBLY, RICHARD H., M.R.C.S., L.S.A., has been appointed to the Honorary Medical Staff of the Newton Abbot Hospital.

HAYDON, EDGAR, M.B., C.M. Glasg., has been appointed to the Honorary Medical Staff of the Newton Abbot Hospital.

HULBERT, J. G., Major, I.M.S., M.B., B.C. Cantab., has been appointed Clinical Assistant to the Samaritan Free Hospital for Women.

HUNT, ERNEST, L.R.C.P., M.R.C.S., has been appointed to the Honorary Medical Staff of the Newton Abbot Hospital.

MACMILLAN, EVAN, M.B., M.S. Edin., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Strathmiglo District of the county of Fife.

MANNERS, W. F., *M.R.C.S. Eng., has been appointed* Clinical Assistant to the Samaritan Free Hospital for Women.

MILLAR, N., *L.D.S. Eng., has been appointed* Honorary Dental Surgeon to the Newton Abbot Hospital.

NISBET, A. THOMSON, M.D., C.M. Glasg., has been appointed to the Honorary Medical Staff of the Newton Abbot Hospital.

PURNELL, R., *M.D. St. And., M.R.C.S., L.S.A., J.P.*, has been appointed a Member of the Visiting Committee for Shepton Mallet and Bristol Prisons.

SCOTT, WALTER H., L.R.C.P. Lond., M.R.C.S., has been appointed to the Honorary Medical Staff of the Newton Abbot Hospital.

SCOTT, W. GIFFORD, M.B., C.M. Edin., L.R.C.S. Edin., has been appointed to the Honorary Medical Staff of the Newton *Abbot Hospital.*

SCRASE, J. J. S., L.R.C.P., M.R.C.S., has been appointed to the Honorary Medical Staff of the Newton Abbot Hospital.

SHIRVELL, EDGAR A., M.R.C.S., L.R.C.P. Lond., has been appointed Resident Medical Officer at the Royal Albert Hospital, Devonport.

SMITH, G. F. DARWALL, B.M., B.Ch. Oxon., F.R.C.S. Eng., has been appointed Surgeon to Out-patients at the *Samaritan Free Hospital* for Women.

STUART, FREDERICK, M.B., B.S. Durh., has been appointed Clinical Assistant to the Samaritan Free Hospital for Women.

SUGDEN, W. A., L.S.A., has been appointed Clinical Assistant to the Samaritan Free Hospital for Women.

WATKINS, JOHN GRANDISSON, L.R.C.P. Lond., *M.R.C.S.*, has been appointed Medical Officer for the North Curry *District by* the Taunton Board of Guardians.

reach of contamination by dogs, dust, &c., and if this cannot be done in certain places it was advised to cover the meat with cloth or waterproof covering. It was also decided to notify all the milk purveyors in the city as to the dangerous and common practice of leaving cans with milk on footways during the process of delivering milk to consumers, the cans and their contents being thus liable to pollution. In the future legal proceedings will be taken in such cases. It is interesting and satisfactory to see all the suggestions made at the Belfast Health Commission gradually adopted by the city authorities.

Jan. 21st.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The School for Nurses at the Salpêtrière.

A SCHOOL for training certificated nurses has been open for two months at the Salpêtrière and is the first of the kind in France. The building consists of a main block and two wings. The course at this institution will be one of two years. The pupils live at the school, where each has her own room; they are not allowed to go out on Sundays unless their families live in Paris or unless they have friends known to the administration; they have one month's holiday in the year besides a few days at New Year and Easter. The number is to be 75 in each year, those of the second year passing out for 75 new ones to take their place. There is a general superintendent with two assistants. The pupils spend their mornings in the wards of the hospital in learning their duties practically, working in turn in all the wards, the children's and adults' and those for maternity, infections, and insane cases. They learn all the details of sick nursing, how to make their patients' beds and their toilet, how to lift them, and so on. They return to the College for *déjeuner* and in the afternoon attend courses of lectures delivered by specially appointed medical men and midwives in the theatre; these courses comprise anatomy, physiology, hygiene, massage, invalid cookery, and all that is included in hospital nursing. The housework and table service are done in turns by the pupils. The uniform is very like that of English nurses. At the end of two years the young women who have successfully passed out of the school, which will be done by examination, will become second-class nurses and will be given their board, lodging, and uniform, and 600 francs a year pay. An intelligent nurse will be able to become a superintendent at the age of 30 years.

Extension of the Hospital for Charity Children.

For some time past the accommodation of this institution has been unable to cope with the calls upon it. To overcome this difficulty the General Council of the Seine has ordered the prefectorial administration to obtain near Paris a piece of land where an extension might be built rapidly and under the best possible hygienic conditions. Such a site has been found not far from Sceaux, in the Antony district. It was occupied by a religious community which has been expelled and the President of the Republic has signed a decree declaring the appropriation of the dwelling of the community to the purposes stated above to be in the public interest. This supplementary building may be opened during the course of next year.

Hæmarthrosis of the Knee.

M. Rochard and M. de Champtaissin communicated to the Surgical Society on Dec. 11th last the result of treating a case of hæmarthrosis of the knee by puncture followed on the next day by active movement against gradually increased resistance. The result was excellent. By increasing progressively the resistance the atrophy likely to result from articular injuries is most effectively met. The treatment has a favourable application to other kinds of effusion into joints.

Resection of the Lower Jaw, with Immediate Mechanical Replacement thereof.

M. Vallas brought this subject before the Surgical Society on Dec. 18th last. After resection of the lower jaw certain complications sometimes occur, such as various forms of ulceration and defects in the dental alignment. M. Vallas has for several years been able to prevent these by fitting an artificial appliance immediately after the operation. This procedure does not give rise to suppuration, and the surgeon can become very expert at fitting suitable appliances to various cases. To get a good result as much tissue as possible must be left and in particular the orbicularis oris which prevents the dribbling of saliva. The classical incision should be extended a little backwards, so that the wound and the scar may not be irritated by the apparatus, and, most important of all, the mouth must be washed out every two hours so that no septic liquid can remain in it.

The Effect of Nervous Stimulants on the Capacity for Work.

At the Academy of Sciences on Jan. 13th M. Armand Gautier made an interesting communication on this subject. He has particularly studied the action of kola on fatigue. In the course of experiments made by giving this drug to a number of horses he found that it apparently diminished fatigue in those that took it. For instance, a horse that ordinarily could go 20 kilometres in an hour went 21 in that time when he had been given the kola. But it was ascertained that at the same time the horse lost more weight than one which had not received any of the stimulant. This shows, according to the learned chemist, that kola, like alcohol, can give the tissues a lash with a whip, but that such energy, artificially provoked, is at the expense of the organism.

A "Rest House" for the French Medical Profession.

For some time past various medical men have had the idea of founding a "rest house" (*maison de retraite*) for French medical men. The idea is now in a fair way to take shape, and upon the initiative of Dr. Courtault and Dr. Nass a committee for consideration of the question has been formed which will hold monthly meetings.

Jan. 21st.

ITALY.

(FROM OUR OWN CORRESPONDENT.)

"Madhouse Administration."

IT is "common knowledge" that Italy cannot cope either with her mendicancy or with her crime. It seems that she is not less impotent to maintain order or even personal safety in her lunatic asylums. Within a few days of each other scenes of violence and even homicide have drawn attention to the "madhouse administration" of two such provincial centres of life, academic and civic, as Turin and Rome herself. The facts are these. In the great Turinese "manicomio" in the Via Giulio, a female inmate, confined to bed by means of powerful straps to prevent her from doing injury to herself or others, contrived to free herself from restraint and at one in the morning, with an iron cross bar taken from her bed, proceeded to the cell of another female also suffering from acute mania and also strapped to her couch, and with two or three well-directed blows fractured the wretched woman's skull and then retired to her own dormitory. These cells form two of a series in a vast corridor of which the only surveillance is intrusted to two women who relieve each other at long intervals. No cry, it seems, on the part of the victim reached the woman on duty, and when the latter entered the cell of the homicide she was suddenly assailed, though providentially the crossbar had been left in the victim's cell. Assistance arrived not a minute too soon, the furious assailant was overpowered and again put under restraint (this time effective), while the victim of her previous aggression on being removed to the hospital was found to have been dead for some hours. The tragic incident of which these details have been made public in the press is now under judicial investigation, while the journals are commenting on the fact that in the Turinese asylum, as in others throughout Italy, the *personnel* is manifestly insufficient. Almost at the same time that this tragedy was in progress the great Roman "manicomio" of the Santo Spirito was the scene of another which, equally savage in detail, was fortunately not fatal. In a ward reserved for the "agitato" (violently excited patients) there was a paralytic man, aged 50 years, who had been giving the attendants trouble. One of these had gone to administer medicine to a patient in another cell, and in his absence a seemingly harmless inmate got access to the paralytic's dormitory and throwing himself upon him with maniacal fury bit off the fleshy part of the nose just above the lip. The victim's cries drew the attendants to the scene. The assailant was overpowered and removed; while the paralytic, if he ever recovers, will bear a hideous disfigurement on his face to his dying day. A week before this deed

DEATH OF A CENTENARIAN IN AUSTRALIA.

IT is stated in the *Australasian* that John Browne, an inmate of the Liverpool Benevolent Asylum, New South Wales, died last month at the reputed age of 119 years. About three years ago he lost his hearing and 18 months later he had a paralytic stroke. He formerly belonged to the British Navy and landed in New South Wales at the age of 32. 20 years ago he entered the asylum, being then 99 years old. His age was fully authenticated by the Asylum authorities.

ARTIFICIAL NOSES.

To the Editor of THE LANCET.

SIR,—Can any of your correspondents tell me of any firm making artificial noses and recommend the work from personal knowledge?

I am, Sir, yours faithfully,

Jan. 22nd, 1908.

M.D.

A COUNTESS'S CURE FOR SMALL-POX.

To the Editor of THE LANCET.

SIR,—In the interesting note under the above heading which appears in your issue of Jan. 18th a passage in the Countess's recipe is given as follows, "as much refined searved (?) through tiffeny." There is evidently a word omitted after "refined" and the word "searved" should undoubtedly be "searched" or "searced," meaning put through a sieve. The word "search" is still a common Scots word for a sieve, or was so at any rate in the early years of the last century. Moreover, the expression "fine searced sugar" will be found constantly in the seventeenth century cookery books.

I am, Sir, yours faithfully,

Jan. 21st, 1908.

ETONENSIS.

Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2 30 P.M.), St. Peter's (2 P.M.).

SATURDAY (1st).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9.30 A.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 20, Hanover-square, W.

MONDAY.—(*Odontological Section*). 7 P.M., Council Meeting. 8 P.M., The Curator: Recent Additions to the Museum. Mr. W. W. James: Some Notes on a Case of Extensive Necrosis of the Mandible. (The patient will be in attendance before the meeting.) Mr. J. F. Colyer: The Treatment of Children from a Dental Aspect (illustrated by the epidiascope).

TUESDAY.—(*Medical Section*). 5 P.M., Dr. C. Thomson: Demonstration of the Use of the Kinematograph in Illustration of Disease. Dr. A. F. Hertz: Pathology and Treatment of Constipation (illustrated by lantern slides). (*Therapeutical and Pharmacological Section*). (Apothecaries' Hall, Blackfriars, E.C.) 4.30 P.M., Prof. W. E. Dixon: Arterio-sclerosis and its Causation. Prof. A. R. Cushing: Nutmeg Poisoning.

THURSDAY.—(*Neurological Section*). 8 P.M., Cases. 8.30 P.M., Discussion on "Tics."

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—8.30 P.M., Mr. C. B. Lockwood: The Use of Chemicals in Aseptic Surgery. Dr. S. West: The Nervous Complications in Acute Pneumonia.

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

THURSDAY.—8 P.M., Card Cases. 8.30 P.M., Mr. S. Snell: (1) Carcinoma of Orbit; (2) Colobroma of Iris in each Eye occurring in Five Generations. Mr. S. Mayou: Microphthalmia resembling Glioma, with Lenticonus and Hypertrophy of the Ciliary Body. Mr. L. Paton: Optic Neuritis in Cerebral Tumours. Dr. A. J. G. Barker: A Case of Suppurative Tenonitis.

BRITISH BALNEOLOGICAL AND CLIMATOLOGICAL SOCIETY, 20, Hanover-square, W.

WEDNESDAY.—5.30 P.M., Adjourned Discussion on Dr. Edgecombe's paper on Blood Pressure in Spa Practice (introduced by Dr. F. Fox) Mr. T. Hawksley: Exhibition of Blood Pressure Instruments.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. J. Galloway: Clinique (Skin). 5.15 P.M., Lecture:—Mr. J. Sherren: The Differential Diagnosis between Injuries of the Spinal Cord and those of Peripheral Nerves.

TUESDAY.—4 P.M., Dr. J. H. Squire: Clinique (Medical). 5.15 P.M., Lecture:—Dr. D. Sommerville: Mucous Colitis.

WEDNESDAY.—4 P.M., Mr. P. J. Freyer: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. W. Langdon Brown: Some Intestinal Intoxications.

THURSDAY.—4 P.M., Mr. Hutchinson: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. L. Williams: The Bogey of Albuminuria.

FRIDAY.—4 P.M., Mr. S. Stephenson: Clinique (Eye).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—12 noon: Lecture:—Dr. Low: Pathological. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Dunn: Diseases of the Eye. 2.30 P.M., Operations. 5 P.M., Lecture:—Mr. Bidwell: Clinical.

TUESDAY.—10 A.M., Dr. Moullin: Gynæcological Operations. 12 noon: Lecture:—Dr. Pritchard: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Dr. Ball: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Operations. Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Dr. E. Jones: The Relation of Insanity to Allied Neuroses.

WEDNESDAY.—10 A.M., Dr. Ball: Diseases of the Throat, Nose, and Ear. Dr. Saunders: Diseases of Children. 2 P.M., Medical and Surgical Clinics. X Rays. Dr. Scott: Diseases of the Eye. 2.30 P.M., Operations. Dr. Robinson: Diseases of Women. 5 P.M., Lecture:—Dr. Beddard: Practical Medicine.

THURSDAY.—12 noon, Lecture:—Dr. Pritchard: Practical Medicine. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Dunn: Diseases of the Eye. 2.30 P.M., Operations. 5 P.M., Lecture:—Mr. Edwards: Clinical.

FRIDAY.—10 A.M., Dr. M. Moullin: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Dr. Ball: Diseases of the Throat, Nose, and Ear. 2.30 P.M., Operations. Dr. Abraham: Diseases of the Skin. 5 P.M., Lecture:—Mr. E. Lloyd: Anæsthetics.

SATURDAY.—10 A.M., Dr. Ball: Diseases of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Dr. Scott: Diseases of the Eye. 2.30 P.M., Operations. Dr. Robinson: Diseases of Women.

NORTH-EAST LONDON POST-GRADUATE COLLEGE, Prince of Wales's General Hospital, Tottenham, N.

MONDAY.—Cliniques:—10 A.M., Surgical Out-patient (Mr. H. Evans). 2.30 P.M., Medical Out-patient (Dr. T. R. Whipham); Throat, Nose, and Ear (Mr. H. W. Carson); X Ray (Dr. A. H. Pirie). 4.30 P.M., Medical In-patient (Dr. A. J. Whiting).

carefully. Quite recently it was announced in the newspapers that three grammes (less than 50 grains) of radium had been obtained at a cost of £2000 from ten tons of pitchblende in that place. This is no doubt an exaggeration, for it may be said that this amount approaches the total quantity of radio-active substance found in Joachimsthal during the last few years. However that may be, nearly all physiological and physical laboratories in Austria, as well as some clinical stations, possess small quantities of the new element which have been placed at their disposal by the Government.

Legislation as to the Certification and Detention of Lunatics.

Several cases of grave mistakes and unlawful detention of persons in lunatic asylums which have happened within the last few years have led to the adoption by a Parliamentary subcommittee of a Bill modifying the present conditions of admission into these institutions. Thus before a person can be put under the control of a trustee on account of his mental condition a judge must make an order, after previously hearing the opinion of duly qualified medical men, some of whom may be selected by the person alleged to be insane. No asylum may receive a patient without the written order of a judge unless the patient seeks admission voluntarily. The detention of a person against his will may not last longer than one year and if prolongation is necessary a new examination of his mental condition by a medical committee is again required.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

Sudden and Violent Deaths in Montreal in 1907.

ACCORDING to the official report of Coroner McMahon of Montreal there were in that city in 1907 785 deaths attributable to accidents, &c. This was just 25 more than in 1906. There were 83 persons killed by railways, of whom 23 were killed by street railways. There were 27 suicides and 50 people met death from drowning. Fire was responsible for 44 deaths, which number includes the deaths of 17 school children and one teacher which took place in a school. There were 12 homicides and 217 sudden deaths. 51 people died without medical treatment and one through an automobile accident. 18 died in gaols, four in the police stations, and one in the patrol wagon. Alcohol caused four sudden deaths and there were 13 from gas asphyxiation and 17 from scalding. During the year there was only one case of manslaughter.

Birth Statistics.

Montreal has a huge birth-rate which is not perhaps exceeded by any other city in the world. It is shown that the birth-rate for 1907 is in the neighbourhood of 44·20 per 1000 of the population. The average of births for a period of 19 years has been 37·92 per 1000. This was for all nationalities, but during this period the birth-rate amongst French Canadians was over 40. The birth-rate in Montreal is higher than in Toronto by 13·21 per 1000, and the excess in comparison with a number of other cities is as follows: Breslau, 5·61; Prague, 13·18; Munich, 5·5; Vienna, 6·5; Milan, 10·0; Rome, 12·3; St. Petersburg, 6·5; London, 8·7; Paris, 16·4; New York, 10·0; and Philadelphia, 13·0. It is satisfactory to record that the proportion of illegitimate children born in the province of Ontario is steadily decreasing. In the year 1900 one out of every 65 of the children born there was illegitimate. Gradually year by year the proportion has been diminishing until in 1905 only one out of every 74·2 was of that unfortunate class. In 1899 the total number of illegitimate births was 808; in 1900, 800; in 1901, 812; in 1902, 819; in 1903, 782; in 1904, 798; and in 1905, 699. The proportion of illegitimates to every 100 children born in these years has been as follows: 1·80, 1·73, 1·76, 1·72, 1·6, 1·58, and 1·34. The comparison with other countries is most favourable, for the latest quinquennial periods return the illegitimate births to every 100 children born as follows: Austria, 14·55; Belgium, 8·51; Norway, 7·35; England, 4·04; Sweden, 10·80; France, 8·26; Scotland, 6·33; Ireland, 2·65; German Empire, 9·21; Prussia, 7·84; and Italy, 6·34. The following statistics are given of the multiple births in Ontario. From 1899 to 1905, both years inclusive, there have been in each of the years in the Province of Ontario twins as follows: 1899, 296; 1900, 401; 1901, 469; 1902, 523; 1903, 492; 1904, 549; and 1905, 526. In the seven years 1899 to 1905 inclusive there have been 29 births in which triplets have occurred. The proportion of male to female births in 1905 shows an increase over the preceding year, the proportion being 100 female to 105 male.

Toronto's Vital Statistics in 1907.

The total number of births registered in Toronto in 1907 was 6715, two a day more than in 1906. The marriage service was performed 3635 times, almost ten times a day, while the messenger of death entered the city 4563 times, nearly 13 times a day. The following is Toronto's record for the past seven years: 1900 (births, marriages, and deaths): 4530, 1789, 3604; 1901: 4445, 2148, 3404; 1902 (not given); 1903: 5040, 2631, 3730; 1904: 5283, 2867, 3884; 1905: 5816, 3060, 3915; 1906: 5985, 3108, 3960; and 1907: 6715, 3635, 4563.

Small-pox Expensive in Ontario.

Owing to neglect on the part of municipalities throughout the province of Ontario to enforce the Vaccination Act and the small-pox regulations it is estimated by Dr. C. A. Hodgetts, secretary of the Ontario Board of Health, that it has cost the province $2,000,000 in the past ten years. During those years the disease has been present throughout the province in more or less of an epidemic form but of a mild character. At the present time there are several centres and just within a few days from 15 to 20 cases were located in one of Toronto's public schools. Ontario now is a largely unvaccinated province and the reflection is on the municipal authorities themselves. If they had enforced the law as they are empowered so to do there would not have been 1 per cent. of the cases that have been reported during the past decade, for 99 per cent. of the cases have been in unvaccinated persons.

Reorganising the Staff of Toronto General Hospital.

Work in connexion with the reorganising of the visiting staff of the Toronto General Hospital is proceeding apace and it is quite apparent from the appointments which have been made and those which are on the *tapis* that this hospital will hereafter be a pure University hospital. There are to be three services in medicine and those who have been appointed heads are: Dr. A. McPhedran, professor of medicine in the University of Toronto; Dr. W. P. Caven, associate professor; and Dr. Graham Chambers, associate in the same University. Mr. I. H. Cameron, M.B., LL.D., F.R.C.S. (honorary), professor of surgery in the University, will be chief of the surgical staff. The heads of the three active services will be Dr. George A. Bingham, Dr. A. Primrose, and Dr. H. A. Bruce, all clinicians of the University Medical Faculty. Dr. R. A. Reeve, dean of the Medical Faculty and Past President of the British Medical Association, is head in ophthalmology; Dr. George R. McDonagh, head of laryngology, otology, and rhinology; Dr. J. F. W. Ross, head of the gynæcological department; Dr. Kennedy McIlraith, head of obstetrics and pædiatrics; and Dr. Samuel Johnston, head of anæsthetics. The assistants to these and the *outdoor* appointments have yet to be made. The chiefs of medicine and surgery are to confine themselves to these specialties and not to do any general practice.

Jan. 12th.

INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Civil Sanitary Reorganisation.

AN important communication was issued on Dec. 4th last by the Government of India, Home Department, to all local governments and administrations upon the subject of sanitary reform in civil areas.[1] It indicates a distinct advance towards the reorganisation of the civil sanitary department on modern lines and will no doubt attract the attention of sanitarians of all kinds at home and abroad.

Snake-bite in Burma.

A Local Government circular issued in Burma states that in view of the large number of deaths occurring annually in Burma from snake-bite it has been decided to distribute as widely as possible through the province the lancets designed by Sir Lauder Brunton for the treatment of snake-bite with permanganate of potassium. The efficacy of this treatment if at once applied is now established. The distribution will be left to the Commissioner of Divisions through

UNIVERSITY OF CAMBRIDGE.—The following degrees were conferred recently:—

M.C.—E. W. Sheaf, Downing.
M.B., B.C.—F. O. Arnold, Trinity.
B.C.—J. H. Ryffel, Peterhouse; B. P. Campbell, Clare; E. Slack, Pembroke; D. W. A. Bull, Gonville and Caius; B. A. I. Peters, Jesus; H. N. Coleman, Clare; N. M. Fergusson, Magdalene; and W. G. Parkinson, Emmanuel.

UNIVERSITY OF BIRMINGHAM.—The following candidates having passed the necessary examinations have obtained the Diploma in Public Health of this University:—

Tom William Beazeley and William Henderson Davison.

LITERARY INTELLIGENCE.—The Walter Scott Publishing Co. will shortly issue a work by Dr. R. R. Rentoul entitled, "Enthetic Diseases (or the Young Man's Peril)."

LONGEVITY.—Mrs. Williams of Sophia-street, Cardiff, has recently reached the age of 100 years.

AFTER-CARE ASSOCIATION.—The next annual meeting of the After-Care Association will be held at 48, Wimpole-street, London, W., by the kind permission of Dr. G. F. and Mrs. Blandford, on Wednesday, Jan. 29th, at 3 P.M. The chair will be taken by Mr. Anthony Hope Hawkins and after the usual business a paper will be read by Dr. G. H. Savage upon the subject of Convalescence from Mental Disorders.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At the ordinary Council on Jan. 16th the diploma of M.R.C.S. was conferred upon John Lawrence Graham-Jones, B.A. Cantab., Cambridge University and St. Thomas's Hospital, and Charles Harold Smith, M.B. *Liverpool*, Liverpool University, who have passed the necessary examinations and have now complied with the by-laws. Licences to practise dentistry were conferred at the same meeting upon Samuel Stephenson Parkinson, Charing Cross and Royal Dental Hospitals, and Wilton Thew, Charing Cross and Royal Dental Hospitals, who have now complied with the by-laws of the College.

INCOME TAX REDUCTION LEAGUE.—A public meeting of the Income Tax Reduction League will be held in the Great Hall, Cannon-street Hotel, at 4 o'clock on Monday, Jan. 27th, when the Right Hon. Viscount St. Aldwyn, the Earl of Kinnoull, the Hon. Herbert C. Gibbs, Sir Alexander H. Brown, Bart., Sir Alexander Henderson, Bart., Professor H. S. Foxwell, and other gentlemen will take part. The Right Hon. Lord Avebury will preside. The aims of the League are: (1) to organise income tax payers for purposes of self-defence; (2) to obtain in times of peace a substantial reduction of the income tax, which ought not to stand at a war rate; and (3) the restriction of income tax to profits actually received by shareholders, or by individual traders, and to exempt depreciation funds from the operation of the tax.

THE CENTRAL POOR-LAW CONFERENCE.—The thirty-sixth annual central conference of the Poor-law authorities of England and Wales will be held in the council chamber of the Guildhall on Tuesday, Feb. 18th, and following day, the Right Hon. Sir Edward Fry, G.C.B., presiding. The Lord Mayor will attend in state and open the proceedings. Sir Edward Fry will then deliver his presidential address. The first day is to be devoted to a discussion on the Relation of Legal Relief and Private Charity, which will be opened by Mr. W. A. Bailward, late chairman of the Bethnal Green board of guardians. A debate is expected on the second day upon the Provision of Work for the Unemployed, opened by Mr. John Kentish Wright (Nottingham) and Mr. Robert Waite (King's Norton), with the Rev. P. S. G. Propert, chairman of the Fulham board of guardians, as selected speaker. The subject of the Treatment of Tuberculosis under the Poor-law will be introduced in a comprehensive paper by Dr. Nathan Raw, physician to the Mill-road Infirmary, Liverpool. Boards of guardians in all parts of England and Wales will, as usual, send delegates, and in addition the 12 Poor-law districts will be officially represented by their members on the central committee, of which Dr. J. Milson Rhodes is chairman, Sir William Chance, Bart., honorary secretary, and Mr. W. G. Lewis (barrister-at-law), secretary.

UNIVERSITY COLLEGE, BRISTOL.—The annual dinner of the University College Colston Society was held on Jan. 14th under the presidency of Mr. G. A. Wills. The chairman announced that his father, Mr. H. Overton Wills, had decided to make a gift of £100,000 towards the fund for the foundation of a university for Bristol and the West of England, provided that a charter be granted within two years. It was stated that £197,000 of the £250,000 required before the charter can be applied for had been subscribed. The guest of the evening was Sir William J. Collins, M.P., Vice-Chancellor of the University of London, who in an interesting speech alluded to the ideals of higher education and added that he considered Bristol had all the elements for the constitution of a vigorous and healthy university.

PROPOSED CONSUMPTION HOSPITAL FOR HEREFORDSHIRE.—At a meeting of the Herefordshire county council on Jan. 11th Sir Richard Harrington moved:—

> That it be referred to the general purposes committee to inquire and report whether it is practicable to establish a county hospital for incipient cases of tuberculosis on the condition of any, and what, payment by the respective boards of guardians throughout the county for pauper patients sent there and to consider the advisability of admitting paying patients.

Sir Richard Harrington said that he thought that a scheme might be adopted whereby the county would not be put to any expense. In other words, the hospital might be made self-supporting. Last year, at a similar hospital in Westmorland, a profit of £359 was made. Mr. George Creswell, who seconded the motion, said that in Herefordshire alone there were 500 persons suffering from consumption. The motion was agreed to.

UNIVERSITY OF LONDON: UNIVERSITY COLLEGE.—A course of eight lectures on the Chemical Constitution of the Proteins will be delivered by Mr. R. H. Aders Plimmer, D.Sc., in the Physiological Laboratory of the College on Wednesdays at 5 P.M., having been commenced on Jan. 22nd. The lectures will deal with the history of the discovery and of the determination of the constitution of the amino acids; the hydrolysis of the proteins and the quantitative determination of the products of hydrolysis; the synthesis of the proteins and the polypeptides; and the action of enzymes on the polypeptides. A course of eight lectures on the Chemistry of the Fats and Carbohydrates will be delivered by Mr. S. B. Schryver, D.Sc., Ph.D., in the Physiological Theatre on Fridays at 5 P.M., commencing to-day (Friday, Jan. 24th). The subject will be considered under the following headings:—The general chemistry of the fats and carbohydrates and the methods of differentiation; the enzymes which act on fats and carbohydrates; the part played by fats and carbohydrates in the general economy of nutrition; and their places of origin and synthesis in animal and vegetable organisms. Both sets of lectures are open to all students of the University of London and also to all qualified medical men and other persons who are specially admitted.

BOOKS, ETC., RECEIVED.

ARNOLD, EDWARD, 41 and 43, Maddox-street, London, W.

The Chemical Basis of Pharmacology. An Introduction to Pharmacodynamics based on the Study of the Carbon Compounds. By Francis Francis, D.Sc., Ph.D., Professor of Chemistry, University College, Bristol, and J. M. Fortescue-Brickdale, M.A., M.D *Oxon.*, *Physician* Bristol Royal Hospital for Sick Children, Medical Registrar Bristol Royal Infirmary, Demonstrator of Physiology, University College, Bristol. Price 14*s.* net.

BAILLIÈRE, TINDALL, AND COX, 8, Henrietta-street, Covent Garden, London, W.C.

years after inoculation, can be proved to be due to renewed activity of the spirochætæ in certain situations there seems to be a fair possibility of their being carried to a third generation. But the question is beset with difficulties, since the sexual purity of two persons up to the time of maturity must be proved, and these are generally persons in whom a tendency to vice is also hereditary; for it is known that a person the subject of inherited syphilis is not immune from re-inoculation after a certain period. Hutchinson mentions eight cases that had come under his observation of persons who presented signs of inherited syphilis and who married but whose offspring showed no evidence of the disease. On the other hand, Edmond Fournier collected 116 cases, 59 of which he thought were to be relied upon as showing transmission to the third generation, and R. W. Taylor has published others. Dr. D. M. Hutton brought a case before this society, which is published in the first volume of our reports and is there criticised by Dr. H. Ashby and others. My own experience is limited to one case but it is of unusual importance as both parents showed most obvious signs of inherited syphilis which were unmistakeable. A blind man attended a school for the blind where he met a blind woman for whom he developed a feeling of affection. They were both blind from interstitial corneo-iritis and they both presented the typical physiognomy of the inherited disease—notched teeth and scars around the mouth. They married, and at the time that the man came under my care their first child was about two months old. The blind wife was brought up to visit her husband, and seeing that she was marked by the same disease I sent for the infant who presented no evidence whatever of syphilis, nor did any symptoms of inherited disease develop in the months during which I was able to keep the child under observation. This case, in which there should have been double inheritance, showed, so long as I was able to watch it, complete immunity.

THE INFANT MORTALITY.

There is probably no disease responsible for such an enormous destruction of human life in its earlier stages as that caused by syphilitic parentage. But my experience shows that this mortality is greatest in those families where both parents have suffered from chancre syphilis and obvious secondaries. The severity of the infection and ineffective treatment, or lack of treatment, are the two factors which determine the mortality. I give two illustrations.

CASE 1.—The mother had been married for 11 years and had suffered three months after marriage from rash and sore-throat. The first child was stillborn 12 months after marriage and was miscarried at the sixth month. The second child lived (the mother being at this time under treatment), but had severe snuffles and rash, was very delicate, and had recurrent sores and eruptions. The third, fourth, fifth, sixth, seventh, eighth, and ninth children were all born at full time but they all died from a few minutes to within two or three months of birth. The tenth child was brought up for treatment suffering severely from snuffles, stomatitis, and coppery shiny eruption. Thus two weak children only were living out of ten.

CASE 2.—The mother three weeks after marriage suffered from sores on the vulva, followed by rash and sore-throat, for which she had no prolonged treatment. She was a pale, cachectic-looking woman. The first child, ten months after marriage, was stillborn at the seventh month. The second was prematurely born at the eighth month and lived for a day. The third, born at full time, a fortnight later came out in large brown spots and had snuffles, and was taken to Guy's Hospital and was there treated by having blue ointment rubbed in over the abdomen. This child is still living, and at the age of eleven years she shows no notching of the incisors or evidence of her inheritance. The fourth child did not come out in an eruption until he was five weeks old. He died at the age of six weeks. The fifth, a boy, came out in an eruption at the age of five weeks and died when he was seven weeks old. The sixth was stillborn. The seventh, prematurely born at the eighth month with an eruption upon her, survived for a day. The eighth, a girl, had a rash soon after birth and she died on the eighth day. The ninth, also a girl, was born healthy, but an eruption came out at the third week. She was treated but she died at the age of 11 weeks. The tenth child, a fine boy at birth, came out in an eruption three weeks after birth and was brought up for treatment. He was suffering from symmetrical squamous syphilide of the legs, the feet, the arms, and the ears, and a little on the body, with ulceration of the mouth and the buttocks and severe snuffles. In this series again there were two children only living out of ten.

THE SECONDARY STAGE.

The trite definition that syphilis is a "fever diluted by time" given by the late Dr. Moxon is applicable to the inherited as well as to the acquired disease. I argued that the primary stage is the separation of the placenta and the infection of the infant through the umbilical vein. The secondary or exanthematous stage commences from the second week to as late as the third month. It is characterised by eruptions which may vary from slight brown macular syphilide to pompholyx, by snuffles, stomatitis, condyloma, wrinkled skin, and wasting, and enlargement of the spleen and liver. Then follow certain changes in the bones, in severe cases perhaps epiphysitis (giving rise to pseudo-paralysis), Parrot's nodes (causing natiform skull and square forehead), cranio-tabes, and bent bones.

It cannot be too strongly insisted upon that the moist eruptions and ulcerations about the mouth and anus as well as the vesicular skin affections are charged with the spirochætæ and are highly contagious. From the second to the sixth year there is commonly a rest in the symptoms that are regarded as characteristic, but the tibiæ may become thickened from periostitis or a joint may become swollen and painful and resolve under mercurial treatment. But now the characteristic physiognomy has been gradually formed, the flattened nose, the square forehead, the radiating lines from the mouth, the stunted figure, and the pallid face; and then during the second dentition we look for the three signs pointed out by our great observer, Jonathan Hutchinson, the notched incisor teeth, interstitial corneitis, and syphilitic deafness. Associated with such signs or occasionally independent of them gummatous destruction of the soft or hard palate may occur and ulcerations of the skin and cellular tissue. Destruction of the nasal bones, caries of the forehead and skull, of the long bones and dactylitis may take place as the result of the inherited disease.

MOON'S MOLARS.

The teeth which Mr. J. Hutchinson described as so characteristic of the disease are the notched and narrowed incisors, especially the central incisors of the upper jaw. This defect is brought about by arrest in development of the central columella, of which each incisor has three. But I wish to draw special attention to the characteristic change brought about by the disease in the first molars described by the late Mr. Henry Moon many years ago, since this change has recently been rediscovered both in America and on the continent. The diagram which I show is taken from the fourth edition of "Bryant's Surgery," published in 1884, wherein the article on Teeth is written by Mr. Moon. He figures and describes the syphilitic first molar as "reduced in size and *dome* shaped through the dwarfing of the central tubercle of each cusp" He also contrasts these teeth with mercurial teeth and syphilitic-mercurial teeth. The change in the molar is of some clinical importance, since occasionally it is characteristic when the incisors are normal.

EYES AND EARS.

The eyes may become affected at an early stage by a choroido-retinitis which may leave permanent changes easily recognised by ophthalmoscopic examination, and iritis, though rare, may occur during the eruptive stage. Interstitial keratitis is most frequent between the ages of six and 16 years but may occur much later and rarely earlier. It is highly characteristic of the inherited disease.

Like the eyes, the ears are attacked by different affections in the early and late stages. During the eruptive stage otitis media may commence as an extension from the inflammation of the naso-pharynx, whilst during the second dentition a progressive deafness of labyrinthine origin may cause complete loss of hearing. Specialists in these departments will, I hope, give us some new facts relative to the syphilitic manifestations in the eyes and ears.

INHERITED SYPHILIS ATTACKING THE VISCERA.

Much work has been done in demonstrating the disease in the various viscera, not one of which appears to be exempt, and there is probably a large field still open here for further investigation. Enlarged spleen and liver associated with rickets may be proved almost invariably to be of syphilitic origin. The disease attacks the various organs in two forms, as a small cell infiltration usually following the course of the vessels, which in its development and decline may lead to

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Belgrave Hospital for Children, Clapham-road, S.W.—House Surgeon for six months. Salary at rate of £20 per annum, with board and lodging.

Birmingham, City of.—Medical Officer (female) for Notification of Births Act. Salary £200 per annum.

Blackburn County Borough, Education Committee.—Assistant Medical Officer of Health. Salary £150 per annum.

Bolingbroke Hospital, Wandsworth Common, S.W.—Surgeon.

Bootle, Borough of, Hospital for Infectious Diseases.—Resident Medical Officer, unmarried. Salary £100 per annum, with board, washing, and apartments.

Brighton, Sussex County Hospital.—Second House Surgeon, unmarried. Salary £60 per annum, with board and residence.

Brighton Throat and Ear Hospital, Church-street, Queen's-road.—Non-resident House Surgeon for six months, renewable. Salary at rate of £75 per annum.

Bristol, University College.—Demonstrator of Physiology.

Cambridgeshire, &c., Asylum, Fulbourn.—Second Assistant Medical Officer, unmarried. Salary £120, rising to £150 per annum, with board, lodging, and attendance.

Cancer Hospital, Fulham-road, London, S.W.—House Surgeon for six months. Salary £70.

Carmarthen, Joint Counties Lunatic Asylum.—Assistant Medical Officer. Salary £200 per annum, with board, lodging, washing, and attendance.

Chesterfield and North Derbyshire Hospital.—Junior House Surgeon. Salary £80 per annum, with board, apartments, and laundry.

City of London Lying-in Hospital, City-road, E.C.—Two Physicians.

Croydon, County Borough of.—Female Assistant to the Medical Officer of Health. Salary £250 per annum.

Devonport, Royal Albert Hospital.—Assistant Resident Medical Officer, unmarried, for six months. Salary at rate of £50 a year, with board, lodging, and laundry.

Great Yarmouth County Borough.—Assistant Medical Officer of Health. Salary £200 per annum.

Hampstead General Hospital, amalgamated with the North-West London Hospital.—Two Physicians and two Surgeons.

Hull, Royal Infirmary.—House Physician-in-Charge, unmarried. Salary £105 per annum, with board and apartments.

Ireland, Lurgan Union Workhouse and Fever Hospital.—Resident Medical Officer (female). Salary £80 per annum, with apartments, laundry, and rations.

King Edward VII. Sanatorium, Midhurst, Sussex.—Junior Assistant Medical Officer, unmarried. Salary £100 per annum, with board, lodging, and attendance.

Leeds Tuberculosis Association.—Resident Medical Officer of Health for the Sanatorium at Gateforth, near Selby, for six months. Salary at rate of £100 per annum, with board, lodging, and washing.

Liverpool Hebrew Tontine Society.—Surgeon.

Montgomery County Council.—Medical Officer of Health. Salary £75 per annum.

Mount Vernon Hospital for Consumption and Diseases of the Chest, Hampstead and Northwood, Middlesex.—Junior Resident Medical Officer. Salary £50 per annum, with board, lodging, &c.

Northampton County Asylum, Berry Wood.—Junior Assistant Medical Officer, unmarried. Salary £150, increasing to £200, with board, lodging, and washing.

Royal Hospital for Diseases of the Chest, City-road, E.C.—Assistant Physician.

Salford, Ladywell Sanatorium.—Assistant Medical Officer. Salary £150 per annum, with apartments and board.

Samaritan Free Hospital for Women, Marylebone-road, N.W.—Honorary Medical and Surgical Registrar.

Seamen's Hospital Society.—Surgeon at Branch Hospital.

St. Pancras and Northern Dispensary, 126, Euston-road.—Honorary Physician.

Stroud General Hospital.—House Surgeon. Salary £100 per annum, with board, lodging, and washing.

Western General Dispensary, Marylebone-road, N.W.—Honorary Surgeon.

Births, Marriages, and Deaths.

BIRTHS.

Last.—On Jan. 12th, at Littlehampton, the wife of Cecil E. Last, M.R.C.S., L.R.C.P. Lond., of a daughter.

Rix.—On Jan. 18th, at 4, Dennington Park-road, West Hampstead, N.W., the wife of Francis W. Rix, M.B., of a son.

DEATHS.

Best.—On Jan. 11th, at Cheltenham, Frederic Arthur Best, M.R.C.S., L.S.A. Lond., aged 69 years.

Gale.—On Sunday, Jan. 19th, John Dakeyne Gale, of 26, St. George's-road, S.W., Senior Partner in the firm of Gale and Company, 15, Bouverie-street, Fleet-street, E.C.

Greaves.—On Jan. 20th, at Eastgate-street, Stafford, Charles Henry Greaves, M.D.

Knaggs.—On Jan. 16th, H. Guard Knaggs, M.D., F.L.S., Lennard-road, Folkestone, in his 75th year.

Pirie.—At 20, Bonaccord-square, Aberdeen, on Jan. 16th, suddenly, Margaret, beloved wife of W. R. Pirie, M.B.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE WINTER EXHIBITION AT THE ROYAL ACADEMY.

To the Editor of THE LANCET.

SIR,—My somewhat belated letter is due to my custom of reserving your classical and art notes—which, I may add, I enjoy hugely and esteem highly—for digestion on the Sunday following publication.

The cause of the letter is to be found in your remarks in THE LANCET of Jan. 11th on the Cowley picture. Anything reflecting even indirectly on Abraham Cowley I feel as if cast on a personal friend, and I would like to be permitted to point out that many of your readers not acquainted with his studies and his life might derive a derogatory opinion of him from your sentence: "Cowley began to study medicine about 1656, and on Dec. 2nd, 1657, he was created M.D. at Oxford 'by order of the Government'—a piece of servility impossible in these days." As hurried journalism such a sentence is permissible and striking, for it is the bare truth; as compared to your classical notes it is sadly wanting in perspective.

As this note is intended for your edification (and perhaps later, if you see fit to correct the impression, for your readers also) may I recapitulate the essential features in Cowley's life which rendered "the order of the Government" not only possible but necessary?

"Entered at Trinity, Cambridge, 1636, B.A. 1639, *minor* Fellow 1640, major Fellow 1642, and M.A. in due course," he was ousted from that stronghold of Puritanism, or at least of Parliamentarism, on account of his strong Royalist opinions and sought refuge from his beloved though Saeva Mater at St. John's College, Oxford, the Royalist centre. We have little or no direct information on his individual studies, but it at least is presumable he began at that time the study of medicine, such as it was, and particularly from his predilection to botany, which then bulked largely in medical studies. Following the train of Queen Henrietta he was absent from England some 12 years, and only returned to be cast into a Cromwellian prison as a spy. Whether he did return with that intention or impelled by the growing fatalism that Cromwellianism was become perpetuated, it is certain that he was a suspected person, "for some time under Trouble, but at length complying (even too much as far as I can learn) with some in power, he got an order to be created M.D. (as he afterwards actually was) at Oxford."

Of course he *got* an "*order*" or otherwise he would not have been permitted to study and qualify at Oxford, released from prison as he was on the bail of Dr. Ch. Scarbrugh for £1000; a bail not abrogated in spite of his compliance.

So far as one can learn he made no use of his medical knowledge in practice, but "in the commencement of the Royal Society, of which an account has been given by Dr. Birch, he appears busy among the experimental philosophers under the title of Dr. Cowley."

My point is that Cowley returned to Oxford to complete studies already commenced in 1642. He was very much blamed for compliance ("even complying too much") and so obtaining his release from prison. The "order" saw to it that Oxford should not reject his attendance on that account and possibly also acted as a deterrent to any Royalists there with whom Cowley might seek to enter into treasonable conversation if there still remained any disposition on his part to act as a secret Royalist agent. Notwithstanding the "order" Cowley remained a "suspect" during the remaining tenure of Puritan Governments, and some even considered his medical studies a mere blind for treasonable practice.

If the "order of Government" had been an act of favouritism towards Cowley, surely he would not have been placed at the same time under a bail of £1000—a very large sum then. That would be a kiss and a blow with a vengeance!

He was known to have been the channel through which all the plotting correspondence of the exiled court for 12 years had been conducted, and having secured his release from prison by compliance with the Puritan Government I think my view of the "order" becomes a very reasonable one. *He was a "suspect" of both parties* explains it in short.

I must hunt up the terms of the "order" some day; it would be an interesting point to university men.

I am, Sir, yours faithfully,

Jan. 19th, 1908. N. CAMPBELL.

SHIP SURGEONS AND VACCINATION FEES.

To the Editor of THE LANCET.

SIR,—Not long ago Brazil, Uruguay, and Argentina passed laws insisting upon the vaccination of passengers before landing, and the shipping companies made their ship surgeons do the extra work without any extra pay, which in one case at least led to a difference of opinion.

Can anyone give information how matters stand at the present time, and whether the question of extra pay for the extra work has been settled in an equitable manner by any of the shipping companies running to South America? I am, Sir, yours faithfully,

Jan. 18th, 1908. BITTEN.

people with embryos in their blood was high; where there was little disease, then the percentage was low. Applying such tests to the different islands and British Guiana, all, with the exception of the latter and Barbados, much the same physically, and all, Barbados and British Guiana included, teeming with the proper intermediate host (culex fatigans) for filaria nocturna, the inequality of the distribution was very marked, reaching a very high percentage in St. Kitts and falling to practically zero in Grenada. The following are the detailed results in order of frequency:—

St. Kitts.—143 cases examined by night; 47 suffering from filaria nocturna disease = 32·8 per cent.; with symptoms 9, without 38. White people of the best class: 23 examined, 7 infected = 30·4 per cent.; with symptoms 3, without 4. Elephantiasis cases: 14 examined, embryos present in 3.

British Guiana.—150 examined by night; 25 suffering from filaria nocturna = 16·6 per cent.; with symptoms 5, without 20. Race characteristics: general population of hospital, negroes, coloured, Portuguese, and whites; 100 examined, 22 infected = 22 per cent.; with symptoms 5, without 17. Coolies (East Indians), 50 examined; 3 infected = 6 per cent.; with symptoms *nil*, without 3. Elephantiasis cases: 15 examined, embryos present in 1.

Barbados.—600 cases examined by night; 76 suffering from filaria nocturna = 12·66 per cent.; with symptoms 27, without 49. Elephantiasis cases: 10 examined, embryos present in none.

Race Characteristics.

Race.	Number examined.	Non-infected.	Infected.	Percentage.
Negroes	401	357	44	10·9
Mulattos	160	142	18	11·2
Whites...	39	25	14	35·3
Total	*600*	*524*	*76*	*12·66*

Trinidad.—400 cases examined by night; 43 suffering from filaria nocturna = 10·75 per cent.; with symptoms 19, without 24. Elephantiasis cases: 83 examined, embryos present in none.

Dominica.—144 cases examined by night; 11 suffering from filaria nocturna = 7 63 per cent.; with symptoms 2, without 9. Elephantiasis cases: 2 examined embryos present in neither.

St. Lucia.—356 cases examined by night; 27 suffering from filaria nocturna = 7·58 per cent. Elephantiasis cases: 5 examined, embryos present in none.

St. Vincent.—100 cases examined by night; 6 suffering from filaria nocturna = 6 per cent.; with symptoms 2, without 4. Elephantiasis cases: 2 examined, embryos present in neither.

Grenada.—174 cases examined by night; none infected = 0 per cent.

Carriacon (a Grenadine).—28 cases examined by night; 1 suffering from filaria nocturna, but this individual was born and had lived in St. Kitts, only having been in Carriacon one year; so deleting him we get a percentage of 0.

Looking into those figures in detail one notices a very great variability in the amount of filarial disease in the different islands, St. Kitts, one of the smaller islands, heading the list; British Guiana, which, of course, is not an island but on the mainland of South America, coming next; Barbados and Trinidad, both densely populated, next; with the smaller islands Dominica, St. Lucia, St. Vincent, and Grenada last. Why this should be is not very clear, and the case of Grenada is so peculiar that I quote the note I made on it on leaving the island. "Filaria nocturnal disease is very rare in Grenada, this answering to the clinical experience of the medical men in the island who state that they very rarely see cases. It does, however, exist and can, as C. fatigans is present. This is exemplified by one case I saw, a man who, though never out of the island, has varicose groin glands and elephantiasis. (Not being able to get his night blood I did not include him in my general list.) Similar other rare cases are to be found, two such having been heard of. In addition to those examined I also saw one Barbadian with elephantiasis and another with filarial embryos in his blood. The marked exemption of the island may be due to the chief town being mainly on a hillside and to there being few mosquitoes of the species C. fatigans present." The medical man at the small village at Carriacon (an island to the north of Grenada) also informed me that he never saw filarial cases there and my figures obtained bear out his statement. During the day and night I spent there I saw one typical case of elephantiasis, however, but he had lived in Trinidad, where he probably got his infection and the individual in whose blood I found embryos as already mentioned had without doubt acquired those in St. Kitts. In my note on Grenada I mentioned there being few mosquitoes (culex fatigans) present, but still I found examples without much difficulty and they were certainly very abundant in St. Lucia, which is also only slightly infected. It is probable that the number of mosquitoes present may have something to do with the prevalence of the disease, St. Kitts, for example, owing to the dirty privy system in vogue there, simply teeming with culex fatigans, and they are also very numerous in Barbados; but considering all things I have come to the conclusion that there is something more subtle at work than this in determining the distribution of this disease. Climate, by that meaning temperature, rainfall, &c., cannot play much part, as it is practically the same in all the islands, and the same might be said of physical characters, though at the same time I think the flat, low-lying, and thickly populated places are specially prone to the disease. Barbados is of coral formation, the other islands volcanic in origin. Looking at other parts of the world, I have found in the Swahilis (coast natives) of Mombasa 13 out of 50 infected with filaria nocturna, none of these showing any symptoms, and this giving a percentage of 26. In Zanzibar it is probably quite as prevalent, because though not making blood examinations there I nevertheless saw plenty of cases with definite symptoms. In Uganda in the interior it is practically non-existent in the indigenous races, as I only found it in one pure Waganda, though in Nubians from the Nile it occurred in 2 per cent., and I also had a well-marked case of elephantiasis in a Nubian woman. Its absence from the interior might probably be due to the absence or scarcity of culex fatigans, but then, again, Mansonia Africana, which Dr. C. W. Daniels easily infected with filaria nocturna experimentally in British Central Africa, abounds in Uganda also. Quoting from the book of our president, Sir Patrick Manson, on the Prevalence of Filaria Nocturna, I note South China given as 10 per cent.; Friendly Islands, 32 per cent. (Thorpe); Samoa, very high; Madras and West Africa, abundant. In Egypt it is present (Sonsino and others) but I do not know if its percentage has ever been accurately determined. Perhaps Dr. F. M. Sandwith may help us in this. In Brisbane in Australia (Bancroft), originally introduced by the Chinese, it seems to have flourished and spread, and it also occurs in Charlestown in North America.

In dealing with the distribution of filaria Demarquayi and filaria perstans we are not on so certain ground as we do not know the proper intermediate hosts of those parasites yet, unless the tick, the ornithodoros moubata, as Wellman believes, acts for the latter. This being so, their irregular distribution may depend on the presence or absence of the proper intermediary, but whether this is the reason or not I can certainly bring forward some remarkable points as regards their prevalence in certain places. Filaria Demarquayi was discovered by Sir Patrick Manson in blood slides sent to him from the West Indies, from St. Lucia and St. Vincent by the late Dr. Otho Galgey and Dr. C. Newsome respectively, and he gave it the above name in honour of Demarquay who first discovered the embryos of filaria nocturna. On arriving at St. Lucia Dr. Galgey informed me that the slides he had sent Sir Patrick Manson were taken from one of the villages of St. Lucia, Gros Islet by name, and that he believed most of the cases of this parasite were to be found there. Accordingly I investigated the subject and found that the belief, with one possible exception, was perfectly correct, the parasite was limited to this one village of the island. St. Lucia has one main town Castries and five subsidiary townships or villages—namely, Soufriere, Vieux-Fort, Dennery, Gros Islet and Anse-la-Raye. On examining the blood of people from these different villages I got the following results. Gros Islet: 62 people examined; 16, or 25·8 per cent., infected with filaria Demarquayi. Soufriere: 78 people examined; 2 infected, those 2, however, being policemen who had lived for periods in Gros Islet. Anse-la-Raye, none. Vieux Fort, none. Dennery: not examined. Castries: 3 infected, 2 of those Barbadians who had lived in different parts of the island, Gros Islet included; the third, a negro, aged 19 years, with the following record. He was born and had lived in Charlestown Nevis till 17 years of age, then went to Castries, then working in the field at a sugar estate, called Roseau, for four months, then back to Castries with fever; has remained in the town since, never in Gros Islet or north of island. It is possible he may have been infected at Nevis before going to St. Lucia. I also saw the infection in a man from a place called Monchy, near Gros Islet, and in another man who had lived all over the island. The one possible exception was Dennery, a small village on the north

TUESDAY.—Clinique:—10.30 A.M., Medical Out-patient (Dr. A. G. Auld). 2.30 P.M., Surgical Operations (Mr. Carson). Cliniques:—Surgical Out-patient (Mr. Edmunds); Gynæcological (Dr. A. E. Giles). 4.30 P.M., Demonstration:—Dr. G. P. Chappel: Selected Medical Cases

WEDNESDAY.—Cliniques:—2.30 P.M., Medical Out-patient (Dr. Whipham); Dermatological (Dr. G. N. Meachen); Ophthalmological (Mr. R. P. Brooks).

THURSDAY.—2.30 P.M., Gynæcological Operations. (Dr. Giles). Cliniques:—Medical Out-patient (Dr. Whiting); Surgical Out-patient (Mr. Carson); X Ray (Dr. Pirie). 3 P.M., Medical In-patient (Dr. G. P. Chappel). 4.30 P.M., Lecture-Demonstration:—Dr. A. J. Whiting: Cases of Aneurysm of the Thoracic Aorta (at the Mount Vernon Hospital Out-patient Department, 7, Fitzroy-square, W.).

FRIDAY.—10 A.M., Clinique:—Surgical Out-patient (Mr. H. Evans). 2.30 P.M., Surgical Operations (Mr. Edmunds). Cliniques:—Medical Out-patient (Dr. Auld); Eye (Mr. Brooks). 3 P.M., Medical In-patient (Dr. M. Leslie).

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—2.15 P.M., Sir Dyce Duckworth: Medicine. 2.30 P.M., Operations. 3.15 P.M., Mr. W. Turner: Surgery. 4 P.M., Dr. StClair Thomson: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat. 4 P.M., Special Lecture:—Dr. StClair Thomson: Mouth Breathing.

TUESDAY.—2.15 P.M., Dr. R. T. Hewlett: Medicine. 2.30 P.M., Operations. 3.15 P.M., Mr. Carless: Surgery. 4 P.M., Mr. M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin. 3.15 P.M., Special Lecture:—Mr. Carless: On Movable Kidney.

WEDNESDAY.—2.15 P.M., Dr. P. Taylor: Medicine. 2.30 P.M., Operations. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical, 11 A.M., Eye.

THURSDAY.—2.15 P.M., Dr. G. Rankin: Medicine. 2.30 P.M., Operations. 3.15 P.M., Sir W. Bennett: Surgery. 4 P.M., Mr. M. Davidson: Radiography. Out-patient Demonstrations:—10 A.M., Surgical and Medical 12 noon, Ear and Throat.

FRIDAY.—2.15 P.M., Dr. R. Bradford: Medicine. 2.30 P.M., Operations. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin. 2.15 P.M., Special Lecture:—Dr. R. Bradford: Diabetes.

SATURDAY.—2.30 P.M., Operations. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

GREAT NORTHERN CENTRAL HOSPITAL, Holloway-road, N.

MONDAY.—9 A.M., Operations (Mr. White). 2.30 P.M., In-patients—Medical (Dr. Beevor); Out-patients—Medical (Dr. Willcox), Surgical (Mr. Low), Eye (Mr. Morton and Mr. Coats).

TUESDAY.—2.30 P.M., In-patients—Medical (Dr. Beale), Throat and Ear (Mr. Waggett); Out-patients—Surgical (Mr. Edmunds), Throat and Ear (Mr. French); Operations (Mr. Beale).

WEDNESDAY.—2.30 P.M., In-patients—Surgical (Mr. Stabb); Out-patients—Medical (Dr. Horder), Gynæcological (Dr. Lockyer), Skin (Dr. Whitfield), Teeth (Mr. Baly); Operations (Mr. Stabb).

THURSDAY.—2.30 P.M., In-patients—Medical (Dr. Morison).

FRIDAY.—3.30 P.M., Lecture:—Dr. C. Lockyer: Cancer of the Womb.

NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC, Queen-square, Bloomsbury, W.C.

TUESDAY.—3.30 P.M., Lecture:—Dr. A. Turner: Cranial Nerve Paralysis.

FRIDAY.—3.30 P.M., Lecture:—Dr. J. Taylor: Myopathies.

ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, Leicester-square, W.C.

THURSDAY.—6 P.M., Lecture:—Dr. M. Dockrell: Syphilis: History and Primary Invasion (Constitutional and Local). Eruptions, Erythematous (I., Macular; and II., Maculo-Papular).

CHARING CROSS HOSPITAL.

THURSDAY.—3 P.M., Demonstration:—Dr. Galloway and Dr. MacLeod: Diseases of the Skin. 4 P.M., Demonstration:—Dr. W. Hunter: Medical. (Post-Graduate Course).

ROYAL INSTITUTION OF GREAT BRITAIN, Albemarle street, Piccadilly, W.

FRIDAY.—9 P.M., Prof. E. Rutherford: Recent Researches on Radio-Activity.

ROYAL SANITARY INSTITUTE, Parkes Museum, Margaret-street, W.

WEDNESDAY.—8 P.M., Discussion on Rivers Pollution, with Special Reference to the Board proposed by the Royal Commission (opened by Sir William Ramsay, K.C.B.).

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index and Title-page to Vol. II. of 1907, which was completed with the issue of Dec. 28th, were given in THE LANCET of Jan. 4th, 1908.

VOLUMES AND CASES.

VOLUMES for the second half of the year 1907 are now ready. Bound in cloth, gilt lettered, price 18*s.*, carriage extra.

Cases for binding the half year's numbers are also ready. Cloth, gilt lettered, price 2*s.*, by post 2*s.* 3*d.*

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months	0 16 3	Six Months	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues; and Agents are authorised to collect, and generally do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

During the week marked copies of the following newspapers have been received:—*Morning Advertiser, Manchester Evening Chronicle, Edinburgh Evening News, Morning Post, Daily Chronicle, The Tribune, Daily Graphic, Liverpool Courier, Manchester Courier, Daily Express, Birmingham Post, Daily News, Manchester Dispatch, Northern Whig, Bournemouth Echo, Westminster Gazette, Cork Examiner, Lymington Chronicle, Poole Herald, Coventry Times, &c.*

people with embryos in their blood was high; where there was little disease, then the percentage was low. Applying such tests to the different islands and British Guiana, all, with the exception of the latter and Barbados, much the same physically, and all, Barbados and British Guiana included, teeming with the proper intermediate host (culex fatigans) for filaria nocturna, the inequality of the distribution was very marked, reaching a very high percentage in St. Kitts and falling to practically zero in Grenada. The following are the detailed results in order of frequency:—

St. Kitts.—143 cases examined by night; 47 suffering from filaria nocturna disease = 32·8 per cent.; with symptoms 9, without 38. White people of the best class: 23 examined, 7 infected = 30·4 per cent.; with symptoms 3, without 4. Elephantiasis cases: 14 examined, embryos present in 3.

British Guiana.—150 examined by night; 25 suffering from filaria nocturna = 16·6 per cent.; with symptoms 5, without 20. Race characteristics: general population of hospital, negroes, coloured, Portuguese, and whites; 100 examined, 22 infected = 22 per cent.; with symptoms 5, without 17. Coolies (East Indians), 50 examined; 3 infected = 6 per cent.; with symptoms *nil*, without 3. Elephantiasis cases: 15 examined, embryos present in 1.

Barbados.—600 cases examined by night; 76 suffering from filaria nocturna = 12·66 per cent.; with symptoms 27, without 49. Elephantiasis cases: 10 examined, embryos present in none.

Race Characteristics.

Race.	Number examined.	Non-infected.	Infected.	Percentage.
Negroes	401	357	44	10·9
Mulattos	160	142	18	11·2
Whites...	39	25	14	35·3
Total	600	524	76	12·66

Trinidad.—400 cases examined by night; 43 suffering from filaria nocturna = 10·75 per cent.; with symptoms 19, without 24. Elephantiasis cases: 83 examined, embryos present in none.

Dominica.—144 cases examined by night; 11 suffering from filaria nocturna = 7·63 per cent.; with symptoms 2, without 9. Elephantiasis cases: 2 examined embryos present in neither.

St. Lucia.—356 cases examined by night; 27 suffering from filaria nocturna = 7·58 per cent. Elephantiasis cases: 5 examined, embryos present in none.

St. Vincent.—100 cases examined by night; 6 suffering from filaria nocturna = 6 per cent.; with symptoms 2, without 4. Elephantiasis cases: 2 examined, embryos present in neither.

Grenada.—174 cases examined by night; none infected = 0 per cent.

Carriacon (a Grenadine).—28 cases examined by night; 1 suffering from filaria nocturna, but this individual was born and had lived in St. Kitts, only having been in Carriacon one year; so deleting him we get a percentage of 0.

Looking into those figures in detail one notices a very great variability in the amount of filarial disease in the different islands, St. Kitts, one of the smaller islands, heading the list; British Guiana, which, of course, is not an island but on the mainland of South America, coming next; Barbados and Trinidad, both densely populated, next; with the smaller islands Dominica, St. Lucia, St. Vincent, and Grenada last. Why this should be is not very clear, and the case of Grenada is so peculiar that I quote the note I made on it on leaving the island. "Filaria nocturnal disease is very rare in Grenada, this answering to the clinical experience of the medical men in the island who state that they very rarely see cases. It does, however, exist and can, as C. fatigans is present. This is exemplified by one case I saw, a man who, though never out of the island, has varicose groin glands and elephantiasis. (Not being able to get his night blood I did not include him in my general list.) Similar other rare cases are to be found, two such having been heard of. In addition to those examined I also saw one Barbadian with elephantiasis and another with filarial embryos in his blood. The marked exemption of the island may be due to the chief town being mainly on a hillside and to there being few mosquitoes of the species C. fatigans present." The medical man at the small village at Carriacon (an island to the north of Grenada) also informed me that he never saw filarial cases there and my figures obtained bear out his statement. During the day and night I spent there I saw one typical case of elephantiasis, however, but he had lived in Trinidad, where he probably got his infection and the individual in whose blood I found embryos as already mentioned had without doubt acquired those in St. Kitts. In my note on Grenada I mentioned there being few mosquitoes (culex fatigans) present, but still I found examples without much difficulty and they were certainly very abundant in St. Lucia, which is also only slightly infected. It is probable that the number of mosquitoes present may have something to do with the prevalence of the disease, St. Kitts, for example, owing to the dirty privy system in vogue there, simply teeming with culex fatigans, and they are also very numerous in Barbados; but considering all things I have come to the conclusion that there is something more subtle at work than this in determining the distribution of this disease. Climate, by that meaning temperature, rainfall, &c., cannot play much part, as it is practically the same in all the islands, and the same might be said of physical characters, though at the same time I think the flat, low-lying, and thickly populated places are specially prone to the disease. Barbados is of coral formation, the other islands volcanic in origin. Looking at other parts of the world, I have found in the Swahilis (coast natives) of Mombasa 13 out of 50 infected with filaria nocturna, none of these showing any symptoms, and this giving a percentage of 26. In Zanzibar it is probably quite as prevalent, because though not making blood examinations there I nevertheless saw plenty of cases with definite symptoms. In Uganda in the interior it is practically non-existent in the indigenous races, as I only found it in one pure Waganda, though in Nubians from the Nile it occurred in 2 per cent, and I also had a well-marked case of elephantiasis in a Nubian woman. Its absence from the interior might probably be due to the absence or scarcity of culex fatigans, but then, again, Mansonia Africana, which Dr. C. W. Daniels easily infected with filaria nocturna experimentally in British Central Africa, abounds in Uganda also. Quoting from the book of our president, Sir Patrick Manson, on the Prevalence of Filaria Nocturna, I note South China given as 10 per cent.; Friendly Islands, 32 per cent. (Thorpe); Samoa, very high; Madras and West Africa, abundant. In Egypt it is present (Sonsino and others) but I do not know if its percentage has ever been accurately determined. Perhaps Dr. F. M. Sandwith may help us in this. In Brisbane in Australia (Bancroft), originally introduced by the Chinese, it seems to have flourished and spread, and it also occurs in Charlestown in North America.

In dealing with the distribution of filaria Demarquayi and filaria perstans we are not on so certain ground as we do not know the proper intermediate hosts of those parasites yet, unless the tick, the ornithodoros moubata, as Wellman believes, acts for the latter. This being so, their irregular distribution may depend on the presence or absence of the proper intermediary, but whether this is the reason or not I can certainly bring forward some remarkable points as regards their prevalence in certain places. Filaria Demarquayi was discovered by Sir Patrick Manson in blood slides sent to him from the West Indies, from St. Lucia and St. Vincent by the late Dr. Otho Galgey and Dr. C. Newsome respectively, and he gave it the above name in honour of Demarquay who first discovered the embryos of filaria nocturna. On arriving at St. Lucia Dr. Galgey informed me that the slides he had sent Sir Patrick Manson were taken from one of the villages of St. Lucia, Gros Islet by name, and that he believed most of the cases of this parasite were to be found there. Accordingly I investigated the subject and found that the belief, with one possible exception, was perfectly correct, the parasite was limited to this one village of the island. St. Lucia has one main town Castries and five subsidiary townships or villages—namely, Soufriere, Vieux-Fort, Dennery, Gros Islet, and Anse-la-Raye. On examining the blood of people from these different villages I got the following results. Gros Islet: 62 people examined; 16, or 25·8 per cent., infected with filaria Demarquayi. Soufriere: 78 people examined; 2 infected, those 2, however, being policemen who had lived for periods in Gros Islet. Anse-la-Raye, none. Vieux Fort, none. Dennery: not examined. Castries: 3 infected, 2 of those Barbadians who had lived in different parts of the island, Gros Islet included; the third, a negro, aged 19 years, with the following record. He was born and had lived in Charlestown Nevis till 17 years of age, then went to Castries, then working in the field at a sugar estate, called Roseau, for four months, then back to Castries with fever; has remained in the town since, never in Gros Islet or north of island. It is possible he may have been infected at Nevis before going to St. Lucia. I also saw the infection in a man from a place called Monchy, near Gros Islet, and in another man who had lived all over the island. The one possible exception was Dennery, a small village on the north

An Address

ON

INHERITED SYPHILIS.

Delivered before the Society for the Study of Disease in Children on Nov. 13th, 1907,

BY R. CLEMENT LUCAS, B.S., M.B. LOND., F.R.C.S. ENG.,

CONSULTING SURGEON TO GUY'S HOSPITAL AND TO THE EVELINA HOSPITAL FOR CHILDREN; MEMBER OF THE COUNCIL OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

GENTLEMEN,—This discussion upon inherited syphilis opens under quite different circumstances from those under which it would have done had it been held three or even two years ago, for it is now generally accepted that the spirochæta pallida discovered by Schaudinn and Hoffmann in 1905 is the true cause of the disease and that mercury, formerly given empirically, is a direct antidote by causing destruction of the parasite.

THE NAME.

This leads me to say a word or two on the three terms applied to this form of the disease: (1) congenital, (2) hereditary, and (3) inherited. Of these three I greatly prefer the third. "Congenital" besides being objectionable in form and suggestion is not universally true; "hereditary" suggests something that may be passed on indefinitely, of which there is no proof; whilst "inherited" implies only something derived from the parents which is detachable, like a fortune or misfortune, and this more correctly expresses the passing on of the spirochætæ to the offspring.

THE MICRO-ORGANISM.

The cause of syphilis, whether inherited or acquired, is the presence in the blood and tissues of the same organism, which can be demonstrated in the various secondary lesions, in the blood, and in the internal organs. The spirochæta pallida is a protozoon of spiral form from 4 to 20 μ in length (about half to three times the diameter of the blood corpuscle) and $\frac{1}{4}\,\mu$ in diameter, with a flagellum at either extremity. It is very motile, and its motility is of three kinds—a lashing, a corkscrew, and a to-and-fro movement. It stains pale pink with Giemsa's fluid, whilst the coarser, highly refracting spirochæta refringens, with which it is often associated, stains dark purple.

THE MODE OF TRANSMISSION.

The discovery of the cause of the disease necessitates the rearrangement of our former views as to its transmission. To those who remember the revolution in thought caused by the discovery of the tubercle bacillus—how that the long-taught diathesis gradually receded into the background and the danger of contagion by intercommunication in houses and families grew into importance—will be prepared for some change of idea in reference to syphilis.

To my mind inheritance from the father alone is *now put* entirely out of court, and it follows that infection of a mother by her syphilitic fœtus can never occur. For how is it possible that a spirochæta which is highly motile and the length of which averages rather more than the diameter of a blood corpuscle, can penetrate an ovum $\frac{1}{120}$th of an inch in diameter and multiply without destroying it. I lay it down as an axiom to be demolished if you will by discussion, *that inheritance is invariably through the syphilised mother*. This is supported by Colles's law that a syphilitic infant cannot cause a chancre on the nipple of his mother when suckling. It would seem that when virulent the spirochætæ penetrate the chorion or placenta and occasion miscarriages, macerated fœtuses, or premature births; but when the virus is attenuated by time or treatment the placenta forms a complete protection to the developing fœtus and it is the separation of the placenta at birth which allows the infection to take place through the umbilical vein. Hence the regularity of the secondary exanthematous stage from a fortnight to three months after birth. *In these cases the separation of the placenta is the first stage and corresponds to the chancre of acquired syphilis.*

COLLES'S LAW.

I alluded to Colles's law (which was first stated in 1837) in support of the argument that the woman was always first syphilised before the embryo or infant. The law is that a woman giving birth to a syphilitic infant cannot be inoculated with syphilis by the infant when she is suckling him—in other words, though the mother may have shown no definite signs of syphilis she is immune; whereas, the syphilitic infant put to the breast of a healthy woman may inoculate her nipple and convey syphilis to her. Hitherto, Colles's law has been used as an argument in support of the view that the mother may get a mild form of syphilis from her syphilitic fœtus whose syphilis is supposed to be derived entirely from the father. But the law of immunity will remain equally true if it be supposed that the mother is first inoculated by the father, a large dose of the protozoon causing an obvious eruptive syphilis, and a small dose a syphilis which misses the eruptive stage.

Syphilis in a man is generally admitted to be capable of transmission to a succeeding generation for a much shorter time than syphilis in a woman, and this supports the view which I have stated—viz., that for transmission, it is necessary that the woman be first infected.

TRANSMISSION BY MILK.

The question whether the milk of a syphilitic female may infect a healthy infant at the breast has been discussed for two and a half centuries, since Ambroise Paré, in the seventeenth century quaintly observed: "Infants suckled by syphilitic nurses are infected by them, seeing that the milk is nothing but whitened blood, which being infected by the virus the child fed with it imbibes the same qualities." Hunter, founding his argument on ineffectual attempts to inoculate the blood of a syphilitic person, came to the conclusion that not only the blood but every secretion derived from it, such as milk, saliva, perspiration, &c., could not convey the disease. But his experiments were inconclusive and his deductions incorrect. Pellizzari succeeded in inoculating the blood of a syphilitic person and, if Voss's experiment is to be trusted, milk has been directly inoculated also.

A remarkable case bearing on this subject I showed before the Royal Medical and Chirurgical Society in 1881. A woman, aged 30 years, gave birth to a healthy child on Dec. 11th, whom *she suckled*. During the following Eastertide her husband inoculated her with syphilis, but she continued to suckle the child. She consulted me three months later, when she was suffering from severe secondaries, squamous eruption, sore-throat, condyloma, and loss of hair, but the child showed no sign of infection. The mother was then treated with small doses of mercury. She and the child were shown when the latter was ten months old. The child had continued to suckle and he remained plump and in perfect health, though the mother still had patches of circinated squamous syphilide on her arms. During the two years that the mother remained under my care for treatment the child showed no sign of inherited syphilis. The importance of this case rests on the fact that the mother had suckled her child for three months after her infection before any treatment was commenced, so that it cannot be argued that the infant was taking the antidote in the mother's milk with the poison and so escaped a source of possible inoculation; but it proves that the milk of a syphilitic woman when received into the alimentary tract of an infant need not convey any infection to the child.

TRANSMISSION BY SEMEN.

It is obvious, as the greater cannot be included in the less, that a spirochæta cannot be carried in a spermatozoon; but this does not exclude the possibility of the spirochætæ being conveyed by the fluid parts of the semen.

The early experiments of inoculation by Mireur failed, but if the recent results obtained by Finger on monkeys be correct the semen of syphilitic men is inoculable. It seems almost necessary that it should be so to account for the cases of inherited syphilis conveyed after the healing of the chancre. If the presence of the spirochætæ could be with certainty demonstrated in the semen of men suffering from recent syphilis much doubt would disappear; and, in the cases where no chancre could be traced in the woman, the probability of the infection being carried through the uterus, after the disintegration of its lining membrane at any menstrual period, would be apparent.

TRANSMISSION TO THE THIRD GENERATION.

Another question much open to discussion is whether syphilis inherited is capable of transmission to the third generation. If the tertiary symptoms, occurring ten or 20

A CASE OF SEVERE ECTHYMA FROM WHICH THE DIPHTHERIA BACILLUS HAS BEEN ISOLATED.

By A. EDDOWES, M.D. EDIN., M.R.C.P. LOND.,
PHYSICIAN TO ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN, LEICESTER-SQUARE, LONDON, W.C.;

AND

J. G. HARE,
PATHOLOGIST AND BACTERIOLOGIST TO ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN.

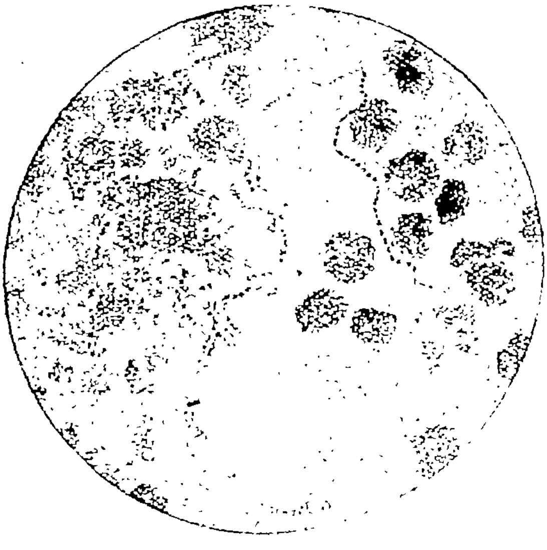
The patient, a girl, aged 11 years, was first seen on Jan. 2nd, 1907. The case was recognised as one of severe type. The contents of a bulla were examined bacteriologically but no streptococcus was found on this occasion. Carbolic lotion and mercurial ointment were prescribed and the patient was told to come again in a week's time. On the 9th the patient showed numerous bullæ on both arms, hands, and lips. Upon the left anterior pillar of the fauces could be seen traces of a ruptured and healing vesicle. There was no false membrane; there was no complaint of sore-throat, though there had been some soreness felt in the throat three days previously. As the child appeared ill and the case was probably being mismanaged at home she was admitted to St. John's Hospital for Diseases of the Skin as an in-patient, but before admission the case was again sent for a careful bacteriological examination. Some uneasiness was felt on account of the patient's general symptoms, but improvement took place at once after she had passed into the hands of the nurses and had all the sores thoroughly dressed with antiseptics; in fact, in 24 hours the patient was quite out of danger and made an uninterrupted recovery. Careful inquiry failed to elicit any plausible origin of the infection. Incidentally it may be mentioned that the child's father is the subject of myxœdema. The child's skin, however, is naturally normal. In May the child was seen and again later and there had not been any relapse.

Bacteriological Report.

1. A small bulla on the right hand was carefully sterilised first with 1 in 20 carbolic acid solution and afterwards with ether and then a sterile platinum needle was inserted and an agar slope inoculation was made with the fluid. From this a growth of staphylococcus aureus with the staphylococcus epidermidis albus was obtained 18 hours later. On plating these two organisms were found to be in pure cultuer.

2. The surface of the bulla was excised and a gentle impression was made on a microscopic slide from the "ceiling" or under surface of the roof of the bulla. This was also scraped with a sterile platinum loop and an agar tube inoculated. The slide was stained with Loeffler's methylene blue and on examination it showed long-chained streptococci, apparently in pure culture (Fig. 1). From the inoculated tube a growth of streptococcus was obtained in pure cultivation. This was again subcultured in broth and a characteristic growth was obtained.

FIG. 1.

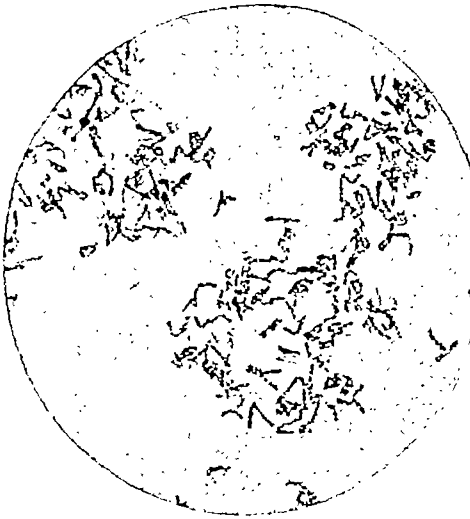


Streptococci. Impression from bulla.

3. A small unbroken pustule on the left hand was then examined. A platinum needle was inserted and two agar-agar tubes inoculated. The growth obtained 18 hours later was typical staphylococcus aureus and albus but together with these, and in separate colonies, there was a thin translucent growth which on smears being made and stained with methylene blue showed a bipolar staining bacillus. The bacilli in parts were only faintly stained; the grouping arrangement was parallel; there were many club-shaped forms, also V-shaped splitting (Fig. 2). The organism reacted to Neisser's stain and it also stained by Gram's method. From this colony two blood-serum tubes were inoculated and the bacillus was obtained in pure culture.

On Jan. 17th, 1907, a 300 gramme guinea-pig was inoculated per peritoneum with two cubic centimetres of serum suspension of this culture. 27 hours later the guinea-pig was dead. On the 19th a post-mortem examination was made, revealing extensive œdema of the peritoneum and hæmorrhages and enlargement of the spleen. Cultures were made from the seat of inoculation and from the heart on blood serum and a growth of this organism was obtained 18 hours later. At the same time a guinea-pig was inoculated with the streptococcus. The organism appears to be non-pathogenic, as up to the time of writing the guinea-pig is still alive. A third guinea-pig, however, being inoculated with the bipolar staining bacillus *plus* the staphylococcus died 72 hours later, and both organisms have been recovered in pure culture. Further inoculations were then made. A guinea-pig was inoculated with 0·75 cubic centimetre of the organisms obtained in pure culture from the guinea-pig. Death occurred 48 hours later, while one inoculated with 1·2 cubic centimetres of culture *plus* 1 cubic centimetre of diphtheritic antitoxin is still alive.

FIG. 2.



Klebs-Löffler bacillus from pustule on the hand.

All the lesions cleared up rapidly under local antiseptic treatment so it was not deemed necessary to employ antitoxin.

In a second case I am indebted to Dr. Alan B. Slater for carrying out the treatment at the patient's own home.

*** The second case referred to by Dr. Eddowes appeared in THE LANCET of Jan. 4th. No mention was then made by Dr. Slater that he was associated with Dr. Eddowes in the case, while we were unaware that the patient came under treatment at the St. John's Hospital for Diseases of the Skin and not at the Farringdon General Dispensary, where Dr. Slater is physician to the Skin Department. Dr. Slater, whose attention we have drawn to the matter, says that the case was handed over to him by Dr. Hargreaves, physician to the St. John's Hospital, whose assistant he was, with full permission for publication.—ED. L.

THE ROYAL SANITARY INSTITUTE.—The List of Honorary Fellows, Members, and Associates elected in January, 1908, includes the following names: Professor Dott. Cavaliere Giuseppe Badaloni, of Rome; Professor Leo Burgerstein, of Vienna; Professor G. W. Chlopine, of St. Petersburg; Professor H. Griesbach, of Mulhausen; Professor Kirchner, of Berlin; Dr. Albert Mathieu, of Paris; Professor M. Mishima, M.D., Principal Medical Officer, Ministry of Education, Tokio; Dr. Luigi Pagliani, Professor of Hygiene, University of Turin; Professor Alb. Palmberg, of Helsingfors; Sir H. H. Pinching, K.C.M.G., late Director-General, Public Health Department, Cairo, Egypt; and Dr. Marc Armand Ruffer, C.M.G.

fibrosis and consequent atrophy, and as a gummatous tumour which is less common. When the inherited disease attacks both testicles or both ovaries at an early age and brings about their fibrosis and atrophy, a condition known as *infantilism* is produced at a period when the sexual characteristics should be pronounced. The physicians present will, I hope, give us much new information on inherited syphilis of the viscera.

THE NERVOUS SYSTEM.

Much difference of opinion exists as to the frequency of nervous disease dependent on inherited syphilis. Whilst some are inclined to attribute every conceivable weakness, paralysis, or mental defect to this disease, others regard the nervous lesions dependent on it as infrequent. A certain proportion of epileptics, deaf-mutes, and idiots, but not a large percentage, show signs of inherited syphilis. On the other hand, syphilitic endarteritis of cerebral vessels, gummata on nerves, and sclerosis of brain and spinal cord have been noticed by competent observers. One of the most interesting observations of late years is that some cases of hydrocephalus are dependent on inherited syphilis and are curable by mercury.

THE NEED OF CRITICISM IN DIAGNOSIS.

In conclusion, I wish to insist on the importance of weighing carefully all the evidence before determining that a particular affection is due to inherited syphilis. Every deformity from dislocated hip to cleft palate, all defects such as hernia, infantile paralysis of various kinds, and even nævi have been described by various writers as dependent on inherited syphilis, and as if better to cover the anomalies the term "para-syphilis" has been invented to add to the confusion.

I need scarcely waste time in combating such crude generalisations as that "all rickets takes origin in syphilis," when any puppy taken from a litter and deprived of proper food and exercise will certainly develop this disease. Equally crude statements have been made as to other diseases. We do not deny that persons whose constitutions have been weakened by disease are liable to produce degenerates in succeeding generations; but in future the most certain test of the disease being syphilis will be the presence of the spirochæta pallida in the part affected. This organism has an extraordinary persistency, producing local symptoms after lengthened periods, but happily we have in mercury and the iodides drugs which control its development and bring about its destruction. Metchnikoff has recently shown that some hours after direct inoculation the application of a calomel ointment to the sore is sufficient to kill the organism and prevent the occurrence of secondary symptoms.

Gentlemen, I have now finished my brief sketch of this interesting disease as it attacks the second generation. It is the merest outline that you may fill in the substance. I ask for new facts and new observations; for now that the cause of the disease is definitely known we have a fresh incentive for further investigation. There are many diseases still confused under a common name—just as gonorrhœa and syphilis, typhus and typhoid fever were confused generations ago—that time will unravel. But as we gain more exact, more precise, and more definite knowledge of any one disease, we shall be the better equipped for appreciating the symptoms and distinguishing the effects produced by others.

THE UNEQUAL DISTRIBUTION OF FILARIASIS IN THE TROPICS.[1]

BY G. C. LOW, M.B., C.M. EDIN.,
LECTURER ON TROPICAL DISEASES, POST-GRADUATE COLLEGE, WEST LONDON HOSPITAL.

THE distribution of any given disease is always a very interesting problem and one which of necessity must depend on many varying factors. This is specially so in many tropical complaints, and such being the case I have hoped by introducing one of those to your attention to-night to stimulate further work and research in the whole question of the unequal distribution of disease throughout the tropics. Most of the well known tropical diseases are peculiar in this respect—namely, that they require an intermediary either in the shape of an animal or an insect to further their proper dissemination, and if theoretically we could remove those then the diseases would necessarily come to an end. Examples of those are plague with its dependency on the rat and its fleas; Malta fever with its dependency on the goat; sleeping sickness conveyed from man to man directly and apparently only by tsetse flies; malaria, yellow fever, and filariasis requiring something more complicated still—namely, a definite extra-corporeal life cycle in different genera of mosquitoes; and so on.

The dictum, "No anopheles, no malaria," is easy of understanding and examples are not far to seek. Barbados, an island in an intensely malarial zone, is free from malaria and the reason of this I showed some years ago was due to anopheles mosquitoes being absent. Rome is now in the same category and other Pacific islands are said also to be free, the danger of the chance introduction of anopheles being exemplified by the present-day condition of Mauritius. If we extend such a dictum further we may say, "No stegomyia fasciata, no yellow fever," and "No culex fatigans or other suitable mosquito, no filaria nocturna." What is slightly more difficult to understand is why a disease should remain localised to certain parts of the world although its intermediate host is much more widely distributed. Why, for example, should yellow fever have remained so particularly endemic to the West Indies and South America when its intermediate host stegomyia fasciata is found throughout the tropics? It is possible that non-introduction of the specific germ is the cause, but behind this may there not be something deeper that we do not yet thoroughly appreciate? Lastly, what is even more difficult to understand is why, given the intermediate host of a disease, suitable climatic conditions, and the presence of abundant chance of the further introduction of the specific parasite, the disease should vary considerably in its distribution, abounding in one place, being scanty in another, or practically absent in a third. Filaria Bancrofti and the diseases it causes follow such an irregular course and it is on this interesting feature that I intend to base my paper to-night.

In dealing with filariasis (including under this term the parasites filaria nocturna, filaria Demarquayi, and filaria perstans) I have probably taken the most difficult of all the tropical diseases because of the tediousness in determining its exact distribution. I may remind you that it is the exception for people infected with filaria Bancrofti to exhibit symptoms, so the only way to arrive at a conclusion of how many individials in a given district are infected is to make exhaustive night blood examinations of the population generally, the same procedure being adopted with the exception that the blood may be taken by day for filaria Demarquayi and filaria perstans. This, as those latter two parasites produce no appreciable clinical signs, you will see is imperative. A group of islands is a suitable area to conduct such observations in for many reasons; they are isolated from each other, many of their inhabitants have never been out of them, the population is not excessive, and as a rule there is one main town with several villages. Recently then when in the West Indies I worked out the percentages of infection with filaria nocturna and filaria Demarquayi in many of the different islands and have tabulated some very interesting results which on the whole may be taken as approximately accurate.

My plan of procedure in this work was as follows. On arrival at an island I inquired from the local medical men if clinical manifestations of filariasis (elephantiasis, lymph scrotum, chyluria, lymphangitis, &c.) were common; then after looking for them myself generally, but of course without specially selecting them for my statistics, I took the night blood from as many of the general population as I could get, obtaining these from the streets, hospitals, prisons, and almshouses, and trying so far as possible to take indigenous natives. In some of the places visited I separated the different races, as this is important, but in others the admixture was so great that this was impossible. Out of the numbers examined I noted how many showed signs of filarial disease or were infected—namely, those with symptoms with or without embryos and those without symptoms but with embryos in the blood. For filaria Demarquayi I examined the different villages in detail as well, sometimes taking the blood by day, sometimes by night, and as those embryos are present at both times, night examinations did both for them and nocturna. The results came out in the following manner: where there was much clinical filarial disease, elephantiasis, &c., then the percentage of ordinary healthy that in cases of cerebral tumour it may be possible by cytological examinations of the cerebro-spinal fluid to distinguish between tumours of tuberculous or syphilitic origin on the one hand and those of different formation on the other. In a tuberculous or syphilitic tumour I should expect to find a lymphocytosis and no such change in a tumour of another source. I have not had an opportunity to verify this. Again, in an ascitic fluid a lymphocytosis points to the effusion being due to tuberculosis.

---

[1] A paper read before the Society of Tropical Medicine and Hygiene on Jan. 17th, 1908.

Predominancy of polymorphonuclear cells.—An excess of polymorphonuclear cells in any serous fluid points to it being of an acute inflammatory origin. These cells can only have been derived from the blood by diapedesis through the vessel walls. Dr. Ross has tabulated 12 cases of acute infective conditions in which he examined the effusions and in all of these he found a very high percentage of polymorphonuclear cells. In two cases of post-basic meningitis these were the principal cells present. It has been proved by many observers that a large number of polymorphonuclear cells in a serous effusion or cerebro-spinal fluid occurs in acute infective conditions. When examining such exudations containing numerous polymorphonuclear cells cytological counts are in many cases not necessary, for the micro-organisms producing the condition are very frequently found in the films. The following are typical counts of the cells in two cases of pleuritic effusion caused by the pneumococcus of Fraenkel :—

Small lymphocytes	22·4	15·0
Polymorphonuclear cells	64·4	81·2
Endothelial cells	13·2	3·8

Only once have I examined cytologically a pericardial effusion and this was one due to the rheumatic diplococcus. The count was as follows: polymorphonuclear cells, 93·2; and small lymphocytes, 6 8 per cent.

The following are examples of cytological counts in four cases of cerebro-spinal meningitis, showing the great predominance of polymorphonuclear cells.

Polymorphonuclear cells	84·0 ...	79·1 ...	85·7 ...	74·6
Small lymphocytes...	15·6 ...	18·6 ...	11·9 ...	24·0
Endothelial cells	0·0 ...	0·6 ...	0·0 ...	0·7
Degenerated or cells not classified	0 4 ...	1·7 ...	2·4 ...	0·7

In two cases of cerebral abscess in which I examined the cerebro-spinal fluid cytologically the differential counts were :—

Polymorphonuclear cells	66·4 ...	97·0
Small lymphocytes	30·5 ...	2·4
Degenerated or cells not classified... ...	3·1 ...	0 4
Endothelial cells	0 0 ...	0·2

The cytodiagnosis in these two cases was of acute meningitis of non-tuberculous origin. With the help of the clinical history of the cases a diagnosis of cerebral abscess was made. In the first case the patient was operated upon by Mr. George Heaton and a large abscess was found in the right temporo-sphenoidal lobe, secondary to ear disease. In the second case the presence of a cerebral abscess was not proved until a post-mortem examination was performed.

Predominancy of endothelial cells.—When there is a large percentage of endothelial cells in a cytological count it indicates that the effusion is mechanical in origin. By mechanical effusion is meant such a one as occurs in serous cavities as a part of a general œdema or in the peritoneal cavity as a result of portal obstruction. Endothelial cells are nearly always present in small quantities in all serous effusions, but it is only when they are in large numbers relative to the other cells that they are of any diagnostic value. In a mechanical effusion the cells present are usually not nearly so numerous as are found in an exudation of acute inflammatory origin and are even much fewer than those found in an exudation due to tuberculosis or syphilis. In two cases, however, I have found them in very large numbers. Sometimes there are seen collections of endothelial cells as though they had been shredded off the serous membranes. These collections of cells or plaques have before now been mistaken for portions of malignant growth.

It has been definitely proved by the observations of Dr. Ross that numerous endothelial cells indicate a mechanical origin for the effusions, notwithstanding the presence of polymorphonuclear cells and small lymphocytes. In ascites due to cirrhosis of the liver numerous endothelial cells are found and the following are typical counts from two cases :—

Endothelial cells	96·4	98·8
Small lymphocytes	3·4	0·2
Polymorphonuclear cells	0·2	0·4
Unclassified cells	0·0	0 6

The difference between an ascites due to cirrhosis of the liver and that due to tuberculous peritonitis can usually be ascertained by a cytological examination. In the former case there would be an excess of endothelial cells and in the latter an excess of small lymphocytes. As tuberculosis of the peritoneum does sometimes occur as a complication of cirrhosis of the liver it may be important that the ascitic fluid be examined.

There is an excess in endothelial cells in all serous effusions occurring in general œdema, but whether this is the case in the cerebro-spinal fluid under such conditions I do not know. I have never examined the cerebro-spinal fluid cytologically in a case of general œdema during life but in one case examined after death I found that the endothelial cells were over 93 per cent. I do not, however, attach importance to this observation as many of the endothelial cells were probably shed into the fluid after death.

Effusions due to malignant disease.—A few observers have stated that it is possible to diagnose the presence of a malignant tumour by a cytological examination of the effusion. This they do by recognising a few cells in the fluid as having been detached from the malignant growth. The recognition of isolated cells in this way is, however, practically impossible and in those cases where a cytodiagnosis of malignant disease has been made it is very probable that the cells considered to be of malignant origin were really endothelial cells after all. Such cells usually predominate in effusions which are caused mechanically by the presence of a neoplasm and often appear in plaques. Unless there be a large collection of the malignant cells in the fluid it must be impossible to diagnose the condition by a cytological examination.

Without doubt a cytological examination of a serous effusion or a cerebro-spinal fluid may be of great help in diagnosis. A diagnosis should not, however, be made on the cytological finding alone, and the examination of the cells in the fluid must only be considered as an additional help in diagnosis. As a general rule it can be relied upon, and only in a very few cases does it mislead. In a very rare case of acute tuberculous cerebro-spinal meningitis published recently in THE LANCET by Dr. T. Stacey Wilson and Dr. James Miller,[2] the cytological examination pointed to the condition being of acute inflammatory origin and not tuberculous, on account of the large percentage of polymorphonuclear cells present. The appearances at the post-mortem examination were all those found in the cerebro-spinal meningitis due to the diplococcus of Weichselbaum, but on microscopical examination numerous tubercle bacilli were found to be present.

Conclusions.—1. Effusions of tuberculous origin contain a large percentage of small lymphocytes, ranging in my series from 59 to 100 per cent. 2. Effusions of acute inflammatory origin contain a large percentage of polymorphonuclear cells, ranging from 64 to 97 per cent. 3. Mechanical effusions contain chiefly endothelial cells, the highest count being 98·8 per cent. 4. Effusions due to malignant disease can rarely be diagnosed by cytological methods alone, but when such a condition is suspected to be present the predominance of endothelial cells would greatly support that view.

Birmingham.

ACID INTOXICATION FOLLOWING ETHYL-CHLORIDE ANÆSTHESIA.

BY H. H. B. CUNNINGHAM, M.D. BRUX.,
F.R.C.S. IREL., M.R.C.S. ENG.,
OPHTHALMIC AND AURAL SURGEON TO THE ULSTER HOSPITAL FOR CHILDREN AND WOMEN, BELFAST; LATE SENIOR CLINICAL ASSISTANT TO THE ROYAL EAR HOSPITAL, LONDON.

ACID intoxication following on general anæsthesia has only been described comparatively recently, but so far as I am aware it has only been recorded as an after-effect of chloroform anæsthesia. Thus in 1894 Dr. Leonard G. Guthrie first drew attention to this subject by his paper on Some Fatal After-effects of Chloroform on Children published in THE LANCET of Jan. 27th (p. 193) and Feb. 3rd (p. 257) of that year. In the Transactions of the Ulster Medical Society for 1906–07 Mr. Robert Campbell, after mentioning the papers published on this interesting subject, coast which I did not examine and it is just possible that filaria Demarquayi might exist there, though Dr. Galgey had never found it in a few examinations he made from there.

---

[2] THE LANCET, Sept. 14th, 1907, p. 763.

In St. Vincent the same striking peculiarity of the parasite being practically localised to one spot occurred. St. Vincent, like St. Lucia, has one main town, Kingstown, and several villages—viz., Calliqua Layou, Barrouallie, Georgetown, and Chateaubelair. I examined blood from all those places with the following results. Calliaqua: 50 examined; 16 infected = 32 per cent. The others were all uniformly negative with the exception of one case from Barrouallie who had lived in different parts of the island, Calliaqua included, and another discovered in Kingstown who had also lived at one period in the infected village. Having had the experience of St. Lucia before me and suspecting that the same might hold good in St. Vincent, my procedure on arrival at the latter place was as follows. I asked Dr. Newsome where he got the blood he sent to London from and he gave me the name of a woman living in Calliaqua. I thereupon visited her (Sept. 21st, 1901) and found her suffering from malarial fever, counting at the same time, however, 40 embryos of filaria Demarquayi in her blood, and making the following note in my record book: "Embryos of F. Demarquayi found in London in 1894 by Dr. Manson." Other inhabitants of the same village examined at the same time showed similar embryos and the infected place being found all that remained was to see if any other parts of the island were infected. In addition to St. Lucia and St. Vincent I also determined the presence of filaria Demarquayi in Dominica, Trinidad, and probably in St. Kitts, but was unable-owing to difficulties of transport and time to find the exact focus in each place. In Dominica two cases were found, one in an old soldier who had served on the West Coast of Africa and had been in the other islands, so he might have got the infection elsewhere; but the other, a mulatto born and living in a place called *Batalie*, had never been out of the island. He suffered from elephantiasis as well—*e.g.*, a double infection —but had no nocturna embryos in his blood. In Trinidad two cases were also found, one in a negro born in *Dominica* who had also lived in St. Vincent and St. Lucia, he therefore being useless; but the other, a case of Dr. Vincents, a girl in the lunatic asylum, born at Matalot, a village in the north of the island, had *never been* out of the island. No further bloods were obtainable from that place, but the one case is sufficient to prove that the parasite is found in Trinidad in the north, though I never found it in the west and south. In St. Kitts, again, two cases were found, one in a man with elephantiasis of the scrotum, a sailor, who had been in Dominica and the other islands; the other in a Portuguese born in Madeira who came to St. Kitts when a youth and had only once been out of the island, when he lived in Port of Spain for a short time. The rest of his life had been spent in Cayon, a village on the windward coast of St. Kitts, so this probably means a focus of infection there.

Looking at the infected villages in St. Lucia and St. Vincent from a physical point of view there was nothing special to be noted in them as different from the other non-infected places. They were both situated on the sea-coast on level ground, with swamps and scrubby bush behind them, and were very malarious. Assuming that a mosquito or other blood insect might be the intermediary many experimental feedings were made with negative results; the only out-of-the-way mosquito noted was at Calliaqua, where the inhabitants told me that a big bright-blue one sometimes was seen. This was the Hæmogogus cyaneus of Williston, but I could only obtain one and it died before I could feed it on a suitable case. Since Wellman's work on the tick as the spreader of filaria perstans appeared I have wondered if such an insect could act as an intermediary for filaria Demarquayi, and this is possible, though even were this so it is strange how it should be so closely limited to one part of the island and not spread universally. Still, ticks of different sorts are very common in the West Indies and the forests of British Guiana and the hypothesis is worth following. It might even be a bug-like tick like the ornithodoros of *Africa*. Filaria Demarquayi is not found in Barbados and I never met with it in Grenada. In British Guiana two embryos are often found in the blood of aboriginal Indians and others living in the backwoods of that colony. One is blunt-tailed and is filaria perstans or a closely allied species, the other is sharp-tailed and may be filaria Demarquaii, though Daniels in comparing the adults believes there are differences, so it may be another species. Those embryos are not found in the blood of people inhabiting the towns or cleared coast lines, only in the forests. The following are statistics on their prevalence. Aboriginal Indians (Arawaks, Caribs, Wainis, Waraus, Akawoios, &c.): 163 examined; 105 infected with sharp- or blunt-tailed embryos = 64·4 per cent. Double infections, 38; blunt-tailed alone 56, sharp-tailed alone 11. Half Indians (*e.g.*, mixtures of Spanish, Portuguese, &c.): 20 examined; 5 infected = 25 per cent. Creoles (*e.g.*, negroes, mulattos, and whites who had lived in the interior): 28 examined; 3, all negroes from the Pomeroon river, only infected. Districts: Pomeroon River, 71 per cent. infected; Cara Cara Creek, Demerara River, 60 per cent. infected; Barima River (Morawhana district), 36 6 per cent. infected; Waini River, 60 per cent. infected. Those figures show that the infection is widespread and pretty equally distributed in the districts examined.

In Africa blunt-tailed embryos (filaria perstans) abound in some districts while they are entirely absent from others, and no one has yet described sharp-tailed embryos on that continent corresponding to the New World forms. What circumscribes their distribution is again difficult to decide; the absence of the suitable intermediate host, if they have to pass through one, would of course preclude them, but probably again other factors play a part. Wellman has lately brought forward some strong evidence that they can undergo a metamorphosis in ticks (ornithodoros moubata) and their distribution seems to coincide except apparently in British Central Africa, where, though the tick is very common, Daniels in some examinations on natives there found no filaria perstans. In the vicinity of the equator, Uganda, and the Congo the parasites are very frequent in the blood of the natives there, in some districts almost everyone having them. The following figures represent such infections in some of the parts I have studied them. Zanzibar and Mombasa, negative; Kavirondo at the east of the Victoria Nyanza, 0 per cent.; Wagandas in Entebbe, 50 per cent. infected; natives of the Sese Islands in the north-west corner of the lake, 86 per cent. infected; natives of Ankole, to the west of the lake, 7·8 per cent. infected; Alurs from Wadelai (Dr. A. W. G. Bagshawe), 8·4 per cent. infected; Nubians from Upper Nile, 6 per cent. infected. From this it will be seen that the Sese Islands in Uganda are a strong focus of infection, the prevalence decreasing to the west, the north, and entirely disappearing by the time the north-eastern shores of the lake are reached. On the western side of the continent it also prevails in many different parts. Mr. T. E. Rice at Ibadon in Lagos found 30 per cent. of the natives infected there, Dr. St. George Gray has informed me that it is fairly common in the hinterlands of Sierra Leone, Dr. Wellman reports it at Benguella, and I have seen it in slides from the Congo and the Nigerias.

A good deal more mapping out and general search for those latter two filariæ in different parts of the world is still required. There may quite conceivably be other species yet undiscovered—*for example* is the sharp-tailed one from New Guinea described by Sir Patrick Manson the same as filaria Demarquaii? The Malay States, Borneo, and Sumatra have not yet been tapped to quote only a few places. It is the tediousness of searching blood slide after blood slide for filariæ that keeps men from working at this subject, and then the further trouble of isolating villages and working them out in detail often adds insurmountable difficulties. Still I think you will agree with me that, after the figures I have collected and given you to-night, the subject of the distribution of all the three filariæ *is extremely* interesting, and if we merely limit ourselves to filaria nocturna alone, which after all is the only one that produces disease, we will still have abundant food for thought and abundant stimulus for research upon the unknown influences which allow it to spread in one place while limiting it in another. By focussing our attention on such a subject we may also indirectly lay bare some of the secrets that surround malaria, yellow fever, beri-beri, and many of the other tropical diseases, and by so doing may open up new fields for the prevention and better control of those scourges of mankind.

Bentinck-street, W.

LONGEVITY.—The death occurred at Brighton last week of the oldest inhabitant of the borough, Mrs. Ann Colwell, who had attained the great age of 101 years and seven months.

growths make their appearance, and early removal of the primary one often prevents their development entirely. Moreover, though surgeons not uncommonly become infected in the course of operations by pyogenic organisms and by the organisms of tubercle and syphilis, and though they must have run the risk many thousand times in the course of operations upon patients suffering from cancer, I am not aware of any single instance in which they have become infected. All the instances in which transplanted cancer germs have succeeded in growing have been cases in which the patients were suffering from cancer already, in whom it may be presumed the power of resistance had been already overcome.

One of the cancer problems is to discover in what this power of resistance may consist. It exists at first apparently in all alike. It must be present and well developed for some considerable time in the tissues around a cancerous growth, but it fails at last, and it fails much more quickly if there is some additional irritant present, such as a suture.

Wimpole-street, W.

TWO CASES OF URETERO-PYELOPLASTY

BY ARTHUR H. BURGESS, F.R.C.S. ENG., M.B., M.SC. VICT.,

HONORARY ASSISTANT SURGEON TO THE MANCHESTER ROYAL INFIRMARY AND MANCHESTER CANCER HOSPITAL; LECTURER IN SURGERY, UNIVERSITY OF MANCHESTER.

THE operation of uretero-pyeloplasty is one which seeks to overcome a constriction at the junction of the renal pelvis and ureter by a procedure analogous to the better known "pyloroplasty"—viz., longitudinal incision through the stricture, followed by transverse suture of the wound. It is indicated in cases of distension of the renal pelvis from stricture at or about the uretero-pelvic junction, provided sufficient healthy renal substance yet remains to justify conservatism. Constriction at this situation may arise from trauma, from the contraction of an ulcer such as may result from the pressure of an impacted calculus, from the contraction subsequent to peri-ureteric or peri-nephritic inflammation, and it is also one of the two less rare sites of congenital stricture, the other being at the entrance of the ureter into the bladder. I regard, for reasons shortly to be stated, the two cases I am now recording to be instances of congenital stricture, leading in the one case to hydronephrosis, in the other to pyonephrosis.

CASE 1.—A female, aged 32 years, was sent to me at the Royal Infirmary with a swelling in the right side of the abdomen. For some months past she had complained of dull aching pains in the right loin, coming on at intervals of about ten days, and one month ago she accidentally discovered the swelling, which she stated had not appreciably altered in size since. She had never noticed anything unusual in the quantity or quality of her urine. The swelling was of about the size of a cocoanut, distinctly fluctuant, freely moveable in any direction, and easily replaceable into the right loin. The urine was acid, of specific gravity 1022, and contained no abnormal constituent. On Feb. 5th, 1907, under chloroform, I cystoscoped the bladder and found it quite healthy, nor were there any differences in appearance between the two ureteric orifices. As the kidneys had temporarily stopped secreting under the influence of the anæsthetic the character of the urinary flow from the two orifices could not be compared. A catheter passed easily along the right ureter for a distance of 11 inches, and was left *in situ*, no urine escaping from it. The patient was then turned over on to her left side and the usual lumbar incision for exposure of the kidney was made. The large cyst was readily exposed and incised, and about 30 ounces of a pale-yellow fluid escaped. The cyst was then separated and brought well up into the wound, when it was found to be the dilated renal pelvis, with the kidney, the calyces of which were comparatively but slightly affected, situated on its outer and posterior aspects. The ureter was readily found by means of the catheter still remaining in it, and which was seen to have passed as far as the junction of the ureter and the distended pelvis, where its further passage had been prevented by a very tight constriction. The ureter was of normal size and there were no signs of any previous peri-ureteritis. A small incision was made on the anterior surface of the pelvis, half an inch above the uretero-pelvic junction, and the constriction was examined from above. With some difficulty a fine wire probe was passed through it from above and the catheter was withdrawn from the ureter. The incision was then continued downwards through the stricture and along the long axis of the ureter for a distance of half an inch. There was no ulceration at the site of the stricture, nor did the mucosa exhibit any scars. This longitudinal wound was then sutured transversely, with two rows of fine catgut, the inner not intentionally including the mucosa. A large rubber drainage-tube was then inserted into the pelvis through the original incision into it and the kidney was fixed to the loin as high up as possible. The external wound was closed around the tube. Five days later the tube was removed and on Feb. 20th the external wound was completely healed. I last saw her on Nov. 12th and could feel the kidney, rather smaller than normal, firmly fixed to the loin. There had been no recurrence of the swelling and the symptoms had been completely cured.

The absence of any signs of cicatricial contraction or other cause to account for the constriction in this case, together with its exact limitation to the uretero-pelvic junction, incline me to regard it as of congenital nature. The absence of hydronephrosis until middle life shows that the constriction was not at first of severe degree. Later the kidney became moveable and consequently no doubt suffered from frequent attacks of congestion which sufficed to aggravate the constriction to an extent sufficient to lead to pelvic distension.

CASE 2.—A female, aged 21 years, was admitted to the Royal Infirmary on Dec. 17th, 1906, complaining of "pains in the back" and "muddy" urine. She had been told that her pains commenced at the age of three years, and she herself did not remember ever being free from them for any length of time. The change in the urine was noticed about three years ago and though slight at first it had steadily become more marked. She had been in hospital several times without material relief. On admission she located her pain to the upper lumbar region of the spine and could not say that it was ever more marked on one side than on the other. The pain always came on in attacks and usually during the night. The abdomen appeared to be tender and palpation was difficult, but I thought palpation over the left kidney was more painful and gave a feeling of greater resistance than that over the right. The urine was 1020, alkaline, contained albumin, no sugar, with a very thick deposit of pus. A radiogram showed an indefinite shadow in the left kidney region. On Dec. 28th I cystoscoped under anæsthesia and found the appearances of general cystitis. Apart from this the right ureteric orifice was unaltered, but that on the left stood prominently out like a pyramid and its margins were extremely swollen and acutely congested. The discharge from the right ureter was apparently clear while that from the left came irregularly and was very turbid. I at once exposed the left kidney from the loin, separated it from its adhesions to surrounding parts, and drew it well up into the wound. The pelvis and calyces were distended with pus. The kidney was incised along its convex border through a dilated calyx and the pelvis was thoroughly flushed out with saline solution. Three small calculi were found inclosed in the lowest calyx and were removed. The ureter was now exposed and was found to be of normal size, but exactly at the uretero-pelvic junction there was a narrow constriction. A small incision was then made in the anterior wall of the pelvis half an inch above this constriction and its upper aspect was inspected. It was treated as in Case 1 by uretero-pyeloplasty, but before closing the incision in the pelvis and ureter a bougie was passed downwards along the latter into the bladder to insure the absence of other obstruction. The pelvis was drained by a rubber tube passed through the original incision in the kidney substance and the organ was fixed to the lumbar wound, a tube being inserted also into the perirenal space below. Shock was rather severe for two days but afterwards the patient steadily progressed. The tubes were retained until Jan. 12th and she left for the convalescent home on the 30th with a small sinus, which finally healed on March 15th. She is now free from the old pains, is in good general health, and the kidney can be felt firmly fixed to the loin and of small size. There is still a small deposit of pus in the urine, which has been acid ever since the operation, but this is gradually diminishing. She can hold her urine for four hours, whereas formerly she passed it as often as every ten minutes.

I think it is probable that in this case also the stricture

THE VALUE OF CYTODIAGNOSIS IN PRACTICAL MEDICINE.[1]

BY JAMES E. H. SAWYER, M.A., M.D. OXON.,
M.R.C.P. LOND.,
CASUALTY ASSISTANT PHYSICIAN AND MEDICAL REGISTRAR, THE GENERAL HOSPITAL, BIRMINGHAM; PHYSICIAN FOR OUT-PATIENTS, THE CHILDREN'S HOSPITAL, BIRMINGHAM.

I PURPOSE in this paper to describe a help to diagnosis which is of considerable value and clinical importance and which might be more extensively made use of than it is at present, as the examination required is one that can be performed by many medical men for themselves. By cytodiagnosis is meant the diagnosis which can often be ascertained by determining the nature of the cells occurring in serous effusion or cerebro-spinal fluid. I do not wish to take credit for having done any original work upon this subject, but while I was pathologist at the General Hospital, Birmingham, and since that time, I have had abundant opportunities of examining the different forms of cells which are found in certain serous effusions and by my observations I have been able to confirm most of the excellent work that has been done on this subject. I should like to take this opportunity to thank the honorary physicians and surgeons of the General Hospital for kindly giving me permission to make use of their cases for this paper. My thanks are also due to the house officers of the hospital for their help in collecting for me the materials from the wards.

It is only during the last eight years that the subject of cytodiagnosis has attracted any notice at all, and during this time only a very few people have taken advantage of it. No advance in the subject was made until 1900, when Widal and Ravaut published a very complete account and showed the relationship between the cytological appearances of the effusions and the clinical diagnosis. A most exhaustive investigation of the value of cytodiagnosis has recently been made by Dr. E. A. Ross at the Louis Jenner Clinical Laboratory, St. Thomas's Hospital, and his work is published in the Transactions of the Pathological Society of London for 1906. All pathological fluids of the body may be examined for the cellular elements they contain, but the fluids with which I propose to deal are pleural serous effusions, cerebro-spinal fluids, and ascitic fluids. Speaking generally, the cells found in all effusions and the percentage of each kind of cell to the total number vary in the same way in all these pathological fluids, according to the disease which produces the effusion.

In making a cytological examination it is necessary to obtain the fluid as soon as possible after it has been removed from the body. After a few hours the cells begin to degenerate and become in consequence very much more difficult to recognise. Some of the fluid should be centrifugalised gently and then the fluid poured off and a film made of the sediment. Care should be taken not to centrifugalise too long or too forcibly or otherwise many of the cells will be destroyed. It is much better to centrifugalise the fluid than to let it stand in a conical jar and then examine the sediment, for the cells degenerate very rapidly. After a film has been made it can be stained at leisure. The two stains I find most useful are Leishman's and Jenner's. The differential count should be made under the one-twelfth oil immersion lens and to get an accurate percentage of the cells 500 should be counted. In many instances, however, and especially in cerebro-spinal fluid of which only a small quantity can often be obtained, it is impossible to count so many on account of the scarcity of the cells. The differences in the percentages of the cells to each other in the various pathological conditions are often so great that usually such a large number of cells need not be counted.

The cells found in serous effusions and cerebro-spinal fluids may be any of those which occur in the blood, as often some blood becomes mixed up with the fluid in its removal from the body, while sometimes the exudation itself contains blood. The cells, however, which we have to consider from the cytological point of view are (1) the small lymphocytes; (2) the polymorphonuclear cells; and (3) the endothelial cells. The small lymphocytes are a little larger than the red blood corpuscles, but they vary considerably in size, and are characterised by a comparatively very large, deep staining, and spherical nucleus. The rim of protoplasm around the nucleus is usually very narrow. The polymorphonuclear cells are considerably larger than red blood corpuscles, usually circular in outline, and with a nucleus variously lobed, so that it may be horse-shoe shaped or resembling the letters E, Z, W, or S. There is a large amount of protoplasm containing minute granules, which give the name of "finely granular oxyphile" to the cell. In effusions these cells are often seen to have burst and their granules lying around. Sometimes they become very degenerated and their nuclei so swollen up that the cells are very difficult to recognise.

Endothelial cells differ greatly from either of the former, but even these in certain circumstances may be confused with small or large lymphocytes. The cells are very much larger than the previous two. The nucleus is large, oval, and slightly irregular in shape, staining as a rule not so deeply as the nucleus of the small lymphocytes. The protoplasm is abundant and the outline of the cell is irregular in shape. These cells may be difficult to distinguish from lymphocytes and also from cells derived from a malignant growth. Mitotic changes can often be seen in the endothelial cells.

When serous exudations or cerebro-spinal fluids are examined very few cells may be present in some cases, and often is this seen in the latter fluids. In health it is usually difficult to find cells in the cerebro-spinal fluid and the presence of many cells, whatever be their nature, is a clear indication of disease. In cerebro-spinal fluids not only the percentage of cells to each other should be ascertained but also any increase in their number must be noticed. Often there are degenerated cells, and other cells which cannot be classified under any of the three heads mentioned above, and so, for the sake of clearness, chiefly those cases are given in this paper in which the cytological count was not complicated by other forms of cells, which when present only occur in very small numbers, and have no practical significance.

Predominance of small lymphocytes.—A large number of small lymphocytes in a cerebro-spinal, pleuritic, or ascitic fluid means that the exudation is due to an irritative process, and that it is not due to any acute inflammatory condition. Thus, in a pleuritic effusion a high percentage of small lymphocytes would point to the condition being due to tuberculosis. This is a very important point, because often it may be very difficult to be certain whether a pleurisy is tuberculous in origin or not. In a well-developed pleurisy of tuberculous origin the differential leucocyte count of the effusion is very characteristic, as may be seen in the following four examples of the condition:—

Small lymphocytes	94·4	90·5	73·4	78·0
Polymorphonuclear cells ...	5·1	7·9	22·2	19·0
Endothelial cells	0·5	1·6	4·4	3·0

In the very early stages of the tuberculous pleurisy this definite cytological picture may not be quite so clear, as the percentage of the lymphocytes is usually not so high; but still they predominate. It is very rare, indeed, for the polymorphonuclear cells to be in excess of the small lymphocytes in pleural effusions, however acute the condition. It is in the tuberculous pleurisies that a cytological examination of the fluid is of such great value. A bacteriological examination might also be made, but the tubercle bacillus is very difficult to detect in a pleuritic effusion and often entails a considerable amount of labour. The absence of the tubercle bacillus in the film would not exclude the tuberculous origin of the disease, but the absence of lymphocytosis would. I have not yet found a lymphocytosis in a pleuritic effusion which was found to be other than tuberculous.

A difficulty arises in cytodiagnosis when the count shows about an equal number of small lymphocytes and polymorphonuclear cells in a pleuritic fluid, but in such a case the important cells to notice are the lymphocytes; and if there is a large number of them the condition is probably due to tuberculosis. The presence of such a large number of polymorphonuclear cells in these cases may be due to an extremely acute onset of the tuberculous pleurisy or to a secondary infection by another organism. In the cerebro-spinal fluid of a child a high percentage of small lymphocytes usually means tuberculous meningitis. A lymphocytosis is also found in locomotor ataxia and any syphilitic disease of the meninges. In five cases of tuberculous meningitis which I examined lymphocytes were practically the only cells present, while in two others they were 75 and 60 per cent. respectively. I should like to suggest operation, but it forcibly illustrates the utility of such a safe and simple surgical procedure where any one muscle or group of muscles is similarly affected by this form of intractable spasm.

NOTE ON THE REMOVAL OF AN OPEN SAFETY-PIN FROM THE ŒSOPHAGUS OF A CHILD AGED FIVE MONTHS.

By DONALD R. PATERSON, M.D. EDIN.,

SURGEON TO THE EAR AND THROAT DEPARTMENT, CARDIFF INFIRMARY.

THIS interesting case with its happy issue[1] raises the question of the proper treatment of foreign bodies in the food and air passages and affords me an opportunity of again putting in a plea for more precise and modern methods of treatment in this important branch of surgery. I agree with Dr. J. S. Manson that in the case he reports it was impossible to get the pin up by means of a probang. But there is a method, unhappily almost entirely ignored in this country, which is scientific, accurate, and safe, by which the extraction of the body might be carried out. I allude to the direct method or œsophagoscopy. I have already[2] discussed its general technique, and in the case in question I need only say that the passage of an œsophagoscopic tube would at once disclose the relations of the foreign body in the gullet. Having ascertained the situation of the point of the pin—in this instance directed upwards—a long fine tube, such as that used in the Killian bronchoscopic forceps, could be passed over it and left *in situ*. Having thus protected the point, the straight forceps which I described in THE LANCET of July 21st, 1906 (p. 155), could be passed alongside of it and the other limb of the pin seized and drawn into the œsophagoscopic tube. If Dr. Manson will try the experiment through a Killian tube he will probably be surprised at the ease and safety with which it can be accomplished. The attempt "to push it down into the stomach and hope for the best" is not without risk, though one recognises that it is difficult to do otherwise when the armamentarium of most of our hospitals, not excepting the large teaching hospitals, is generally limited to a probang and a more dangerous coin-catcher. I have known serious damage done to the gullet by a probang and I have extracted sharp-pointed bodies which were so situated at the cardiac end of the œsophagus that an effort to push them down would inevitably have caused grave injury. On the other hand, an attempt to pull them up by a coin-catcher is often more dangerous. With small rounded bodies such as coins which can be localised by a skiagram its use may be justifiable, but where sharp substances such as pieces of bone lie in the gullet serious damage may be inflicted and cases have occurred when fatal results have followed a rent made in the œsophageal wall. But whether these efforts are successful or not is a matter of pure chance; they are done in the dark, and therefore to be discountenanced, for it is surely preferable to work under control of the eye.

These remarks apply with even more force to foreign bodies in the air passages. Their rational treatment makes but slow progress. A collection of 200 cases of bronchoscopy for foreign body made from medical literature from its inception nine years ago to the present time shows few, very few, from English sources. For this our teaching authorities have to bear some responsibility. The newer methods are not put into practice, and so lo[illegible]ons in our [illegible] centres think the only treatment is to lay open the trachea "and hope for the best," so long will this important branch remain a reproach to English surgery.

Cardiff.

A CASE OF ACUTE PULMONARY ŒDEMA.

BY W. B. SILAS, M.R.C.S. ENG., L.R.C.P. LOND.

IN view of the correspondence in the columns of THE LANCET it may be of interest to record another case of acute pulmonary œdema. The patient, a girl, aged 14 years, was brought to my notice on Jan. 4th with a slight tonsillitis. This was the fourth patient in that house who was affected with tonsillitis, but the affection, so far as the first two were concerned, was of a severe type and almost entirely unilateral in character. The patient to whom this note refers had nothing more than a slight congestion of the throat with a temperature of 99° F. Incidentally it was mentioned that during the last four weeks she was at times short of breath on exertion and occasionally puffy about the face and legs. The heart and lungs were examined and were then found to be normal; there was no œdema anywhere to be seen. A specimen of the urine was not sent on that day as requested but on the evening of the 5th; it was then found to be loaded with urates and about one-eighth albumin. As soon as the albuminous nature of the urine was discovered the patient, who had previously kept in her room, was ordered to bed and the case was treated as one of Bright's disease. On the 7th (the fourth day of my attendance on her) there was distinct puffiness of the face and both legs; fine crepitations were discernible in the lungs but only at the bases. That examination was made at 1.30 P.M. The quantity of urine collected in the previous 24 hours was about 12 ounces, but as there was diarrhœa that quantity was below the real amount passed. About four hours after that visit an urgent message came for me to go to the patient as she was much worse. She was then found sitting up in bed gasping for breath and extremely cyanosed, whilst from her mouth and nostrils a profuse frothy blood-stained fluid was pouring. A $\frac{1}{100}$th of a grain of nitro-glycerine was administered subcutaneously and as the case was regarded as one in which venesection was called for the patient was left for 20 minutes while I fetched suitable instruments. On my return she seemed better, but relapsed again, so from eight to ten ounces of blood were drawn off from the right median basilic vein. No real improvement followed the venesection, so two more hypodermic injections of nitroglycerine ($\frac{1}{100}$th of a grain each) were administered at intervals of half an hour. The patient died at 9.45 P.M., about four and a quarter hours after the onset of the attack.

The only thing which seemed to benefit the condition was the first hypodermic injection of nitroglycerine. The previous history of the patient was diphtheria three years ago and chorea about 15 months ago.

PATHOLOGICAL SECTION.

Diffuse Cancellous Osteoma of the Femur.—Tuberculous Endocarditis.—Effects of Calculi upon Photographic Plates in the Dark.—Malignant Disease of the Rectum.—Chimney-sweep Carcinoma.

A MEETING of this section was held on Jan. 21st, Mr. S. G. SHATTOCK, the President, being in the chair.

Mr. W. H. BATTLE and the PRESIDENT gave an account of a remarkable case of Diffuse Cancellous Osteoma of the Femur following a Fracture in [illegible] which similar growths afterwards developed in connexion with other bones. A section of the original tumour was shown with microscopical sections of the growth and several skiagrams showing the structure and position of the growths were also exhibited. The patient, a boy aged four years, was in St. Thomas's Hospital in 1901 for a tumour of the left femur. The

THE VALUE OF CYTODIAGNOSIS IN PRACTICAL MEDICINE.[1]

BY JAMES E. H. SAWYER, M.A., M.D. OXON., M.R.C.P. LOND.,

CASUALTY ASSISTANT PHYSICIAN AND MEDICAL REGISTRAR, THE GENERAL HOSPITAL, BIRMINGHAM; PHYSICIAN FOR OUT-PATIENTS, THE CHILDREN'S HOSPITAL, BIRMINGHAM.

I PURPOSE in this paper to describe a help to diagnosis which is of considerable value and clinical importance and which might be more extensively made use of than it is at present, as the examination required is one that can be performed by many medical men for themselves. By cytodiagnosis is meant the diagnosis which can often be ascertained by determining the nature of the cells occurring in serous effusion or cerebro-spinal fluid. I do not wish to take credit for having done any original work upon this subject, but while I was pathologist at the General Hospital, Birmingham, and since that time, I have had abundant opportunities of examining the different forms of cells which are found in certain serous effusions and by my observations I have been able to confirm most of the excellent work that has been done on this subject. I should like to take this opportunity to thank the honorary physicians and surgeons of the General Hospital for kindly giving me permission to make use of their cases for this paper. My thanks are also due to the house officers of the hospital for their help in collecting for me the materials from the wards.

It is only during the last eight years that the subject of cytodiagnosis has attracted any notice at all, and during this time only a very few people have taken advantage of it. No advance in the subject was made until 1900, when Widal and Ravant published a very complete account and showed the relationship between the cytological appearances of the effusions and the clinical diagnosis. A most exhaustive investigation of the value of cytodiagnosis has recently been made by Dr. E. A. Ross at the Louis Jenner Clinical Laboratory, St. Thomas's Hospital, and his work is published in the Transactions of the Pathological Society of London for 1906. All pathological fluids of the body may be examined for the cellular elements they contain, but the fluids with which I purpose to deal are pleural serous effusions, cerebro-spinal fluids, and ascitic fluids. Speaking generally, the cells found in all effusions and the percentage of each kind of cell to the total number vary in the same way in all these pathological fluids, according to the disease which produces the effusion.

In making a cytological examination it is necessary to obtain the fluid as soon as possible after it has been removed from the body. After a few hours the cells begin to degenerate and become in consequence very much more difficult to recognise. Some of the fluid should be centrifugalised gently and then the fluid poured off and a film made of the sediment. Care should be taken not to centrifugalise too long or too forcibly or otherwise many of the cells will be destroyed. It is much better to centrifugalise the fluid than to let it stand in a conical jar and then examine the sediment, for the cells degenerate very rapidly. After a film has been made it can be stained at leisure. The two stains I find most useful are Leishman's and Jenner's. The differential count should be made under the one-twelfth oil immersion lens and to get an accurate percentage of the cells 500 should be counted. In many instances, however, and especially in cerebro-spinal fluid of which only a small quantity can often be obtained, it is impossible to count so many on account of the scarcity of the cells. The differences in the percentages of the cells to each other in the various pathological conditions are often so great that usually such a large number of cells need not be counted.

The cells found in serous effusions and cerebro-spinal fluids may be any of those which occur in the blood, as often some blood becomes mixed up with the fluid in its removal from the body, while sometimes the exudation itself contains blood. The cells, however, which we have to consider from the cytological point of view are (1) the small lymphocytes; (2) the polymorphonuclear cells; and (3) the endothelial cells. The small lymphocytes are a little larger than the red blood corpuscles, but they vary considerably in size and are characterised by a comparatively very large, deep staining, and spherical nucleus. The rim of protoplasm around the nucleus is usually very narrow. The polymorphonuclear cells are considerably larger than red blood corpuscles, usually circular in outline, and with a nucleus variously lobed, so that it may be horse-shoe shaped or resembling the letters E, Z, W, or S. There is a large amount of protoplasm containing minute granules, which give the name of "finely granular oxyphile" to the cell. In effusions these cells are often seen to have burst and their granules lying around. Sometimes they become very degenerated and their nuclei so swollen up that the cells are very difficult to recognise.

Endothelial cells differ greatly from either of the former, but even these in certain circumstances may be confused with small or large lymphocytes. The cells are very much larger than the previous two. The nucleus is large, oval, and slightly irregular in shape, staining as a rule not so deeply as the nucleus of the small lymphocytes. The protoplasm is abundant and the outline of the cell is irregular in shape. These cells may be difficult to distinguish from lymphocytes and also from cells derived from a malignant growth. Mitotic changes can often be seen in the endothelial cells.

When serous exudations or cerebro-spinal fluids are examined very few cells may be present in some cases, and often is this seen in the latter fluids. In health it is usually difficult to find cells in the cerebro-spinal fluid and the presence of many cells, whatever be their nature, is a clear indication of disease. In cerebro-spinal fluids not only the percentage of cells to each other should be ascertained but also any increase in their number must be noticed. Often there are degenerated cells, and other cells which cannot be classified under any of the three heads mentioned above, and so, for the sake of clearness, chiefly those cases are given in this paper in which the cytological count was not complicated by other forms of cells, which when present only occur in very small numbers, and have no practical significance.

Predominancy of small lymphocytes.—A large number of small lymphocytes in a cerebro-spinal, pleuritic, or ascitic fluid means that the exudation is due to an irritative process, and that it is not due to any acute inflammatory condition. Thus, in a pleuritic effusion a high percentage of small lymphocytes would point to the condition being due to tuberculosis. This is a very important point, because often it may be very difficult to be certain whether a pleurisy is tuberculous in origin or not. In a well-developed pleurisy of tuberculous origin the differential leucocyte count of the effusion is very characteristic, as may be seen in the following four examples of the condition:—

Small lymphocytes...	94·4	... 90·5	... 73·4	... 79·0
Polymorphonuclear cells ...	5·1	... 7·9	... 22·2	... 18·0
Endothelial cells	0·5	... 1·6	... 4·4	... 3·0

In the very early stages of the tuberculous pleurisy this definite cytological picture may not be quite so clear, as the percentage of the lymphocytes is usually not so high; but still they predominate. It is very rare, indeed, for the polymorphonuclear cells to be in excess of the small lymphocytes in pleural effusions, however acute the condition. It is in the tuberculous pleurisies that a cytological examination of the fluid is of such great value. A bacteriological examination might also be made, but the tubercle bacillus is very difficult to detect in a pleuritic effusion and often entails a considerable amount of labour. The absence of the tubercle bacillus in the film would not exclude the tuberculous origin of the disease, but the absence of lymphocytosis would. I have not yet found a lymphocytosis in a pleuritic effusion which was found to be other than tuberculous.

A difficulty arises in cytodiagnosis when the count shows about an equal number of small lymphocytes and polymorphonuclear cells in a pleuritic fluid, but in such a case the important cells to notice are the lymphocytes; and if there are a large number of them the condition is probably due to tuberculosis. The presence of such a large number of polymorphonuclear cells in these cases may be due to an extremely acute onset of the tuberculous pleurisy or to a secondary infection by another organism. In the cerebro spinal fluid of a child a high percentage of small lymphocytes usually means tuberculous meningitis. A lymphocytosis is also found in locomotor ataxia and any syphilitic disease of the meninges. In five cases of tuberculous meningitis which I examined lymphocytes were practically the only cells present, while in two others they were 75 and 60 per cent. respectively. I should like to suggest technical knowledge, therefore inexperienced assistants should wear gloves. The skin of the patient was cleansed by treating it alternately with the spirit and biniodide lotion and the watery solution of biniodide of mercury for not less than three minutes, acting on the assumption that asepsis depended upon saturating the skin itself. Infection from the atmosphere might be better described as environment infection, for throat bacteria were coughed long distances and boots introduced into the operating-theatre much filth crowded with equine intestinal bacteria. Coughing audiences might be screened off and the air of the theatre might be improved by ventilation, but it was a costly process. In conclusion, Mr. Lockwood said that judging from the clinical results of his own operations he could not allow that ill results followed the use of dilute chemical antiseptic solutions.—Mr. T. H. KELLOCK said that they had heard a great deal about surgeons giving up the old methods of antiseptics, but he trusted in the use of mild antiseptics which up to the present time had not failed him.—Mr. LOCKWOOD then replied.

---

[1] A paper read before the Midland Medical Society on Oct. 16th, 1907.

Dr. SAMUEL WEST read a paper on Nervous Phenomena in Pneumonia. He said that few cases of pneumonia ran their course without nervous phenomena of some kind. They generally occurred during the acute stage, were transient, and of toxic origin. Rigor was due to the sudden upset of physiological equilibrium owing to the acute onset of the disease and was single and severe. If the onset were less abrupt shivering might be repeated. In children, when replaced by fits and followed by unconsciousness it might suggest meningitis. Insomnia might be extreme and was likely to be followed by prostration, and opiates might be necessary. Hiccough was a rare but grave symptom. Delirium if active, as in delirium tremens, might end in great exhaustion and death. It was most marked in children and in drinkers and in apex pneumonia. If long continued it was of bad prognosis. Wandering at night might set in after the crisis and was then an indication for stimulants. The knee-jerk, normal for the first day or two, disappeared on the third or fourth day, remained absent till the ninth, and returned to the normal at the end of the second week. It stood in no relation to the crisis and disappeared early in bad cases and late in mild ones. Hughlings Jackson first described the absence of knee-jerk in pneumonia in 1894. Subsultus tendinum and muscular tremors occurred only in grave asthenic cases. Acute tympanites was a neuromuscular paralysis and of fatal omen. General cutaneous hyperæsthesia was rare but not so rare locally. Spinal irritation sometimes appeared as tremors or spasms produced by movement. Stiffness of the back and neck, retraction of the head, and arching of the back might suggest cerebro-spinal meningitis. The symptoms were only present in the early hours of the attack and disappeared on the second day or so. Transient paralyses of the limbs and face, aphasia, and eye disturbances might occur but were very rare. Meningitis which might start during the acute stage might last after it. It was often found post mortem when not suspected during life. Epidemic cerebro-spinal meningitis was frequently complicated with pneumonia and the spinal symptoms of pneumonia might simulate it, but the two diseases were distinct. Hemiplegia, except in the transient cases referred to, was due to thrombosis or embolism. Infective endocarditis might develop as in other specific fevers. Mental defects, mania, melancholia, &c., might follow pneumonia. As a rule they were recovered from in time. Peripheral neuritis might follow as in cases of diphtheria but, like them, ended in recovery. Nervous phenomena played a more important part in pneumonia than was usually assigned to them.—The PRESIDENT said that they had yet to learn the clinical aspects of the different forms of pneumonia. He agreed with Dr. West in regard to the importance of obtaining sleep in the circumstances indicated but pointed out the necessity of avoiding narcotics as far as possible. He related a case in which hiccough was relieved by a hypodermic injection of morphine. Concerning the use of alcohol in pneumonia he said that the longer experience he had the less he ordered stimulants.—Dr. F. DE HAVILLAND HALL remarked on the fact that head symptoms were particularly pronounced in cases of apical pneumonia.—Dr. E. CAUTLEY said that it was uncommon to find true pneumonia in children commencing with fits. In his opinion, by far the most usual symptom was vomiting in place of the rigor seen in adults. Nervous phenomena were rare and before accepting them as due to simple pneumococcal pneumonia it must be made clear that they were not due to influenzal pneumonia. He did not advise the administration of alcohol in pneumonia except to aged patients at the time of the crisis.—Dr. F. J. POYNTON said that he had noticed occasionally after pneumonia that there was an extraordinary slowing of the pulse which might drop to 40 or 50 beats per minute and that condition might last for a few days. He described two cases of pneumonia in which permanent hemiplegia had resulted.—Dr. WEST, in reply, said that alcohol was unnecessary in the treatment of pneumonia but in cases of dangerous collapse its timely administration was useful. The occurrence of hemiplegia after pneumonia was due, he thought, to an infective arteritis which was not limited to the brain. He knew of a case in which such infective arteritis had caused the loss of two fingers.

SOCIETY OF TROPICAL MEDICINE AND HYGIENE.

The Unequal Distribution of Filariasis in the Tropics.

A MEETING of this society was held on Jan. 17th, Sir PATRICK MANSON, the President, being in the chair.

Dr. G. C. LOW read a paper on the Unequal Distribution of Filariasis in the Tropics, which is printed on p. 279 of this issue of THE LANCET.

Dr. L. W. SAMBON suggested that unequal distribution of filariasis was due to hyperparasitism.

Dr. R. T. LEIPER said that from observations which he had made on a recent expedition he was able to confirm Dr. Low's work in regard to the presence of filaria perstans in the blood of natives round Entebbe. When the adult form came to be examined it might be found that there were two or three species in filaria Demarquayi.

Dr. F. M. SANDWITH described his experiences in regard to filariasis in Egypt.

The PRESIDENT said that the paper showed how the more that was learned about filariasis the wider the field for investigation became. He did not consider that the propagation of the filaria was restricted by hyperparasitism. Until they studied the mature worm it was impossible to settle from the embryo the whole truth of the matter.

Dr. LOW, in reply, admitted the difficulty of identifying the species from the embryo and urged that there must be something more in the question that they did not understand to explain the distribution of filariasis.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

The Chemistry, Pharmacology, and Therapeutics of Ergot, Strophanthus, Squill, and Digitalis.—Medical Student Life at Montpellier in the Middle Ages.—Exhibition of Cases and Specimens.

A MEETING of this society was held on Jan. 17th, Dr. J. ALLAN being in the chair.

Dr. J. GORDON SHARP read a paper on the Chemistry, Pharmacology, and Therapeutics of Ergot, Strophanthus, Squill, and Digitalis, with special reference to recent research. Speaking first of ergot, he said that it was one of those drugs which was both praised and abused, but the best proof of its usefulness was to be found in the fact that it had found a place in all pharmacopœias. Although much work had been done on its chemistry not any advance had been made since Tanret described pure inert crystalline ergotonine till 1906 when Barger and Carr confirmed Tanret's work on ergotonine, and in addition they obtained Tanret's amorphous toxic ergotonine in a pure state and had succeeded in forming crystalline salts of the same. On account of its toxic action, which had been investigated by Dale, a Cambridge graduate working in the Wellcome Research laboratories, it was renamed ergotoxine. This toxic ergotoxine could be readily converted into the inert ergotonine, and conversely inert ergotonine could be converted into poisonous ergotoxine. Ergotoxine was a hydrated ergotonine, and Kraft, a German investigator, who, independently of Barger and Carr, isolated the pure toxic alkaloid, called it hydro-ergotonine instead of ergotoxine. Ergotonine in the pure state was inert, but it was just possible that in certain states of the tissues a small portion of it might be converted into potent ergotoxine. However, it was describes in detail three cases with the post-mortem appearances. But in this communication every case described followed chloroform administration. My case shortly is as follows:—

A well-developed, bright-looking, and apparently healthy girl, aged six years, was admitted to hospital for deafness owing to the presence of adenoids. On the morning of Nov. 13th, 1907, after having been prepared in the usual manner, ethyl chloride was administered and the adenoids were removed, the operation, including administration of the anæsthetic, taking about a minute; the child recovered completely and was then placed in bed. Towards evening she vomited twice but slept well during the night and no vomiting occurred. On the next day she complained of severe headache and of nausea. She retched a good deal during the day and vomited a few minutes after taking any food, so she was given some bismuth mixture in the evening. During the night she slept fairly well but vomited once, whereupon the medicine was repeated. On the 15th she complained of violent frontal headache and vomited immediately after taking anything by the mouth. Towards evening the pulse became rapid and small and the child felt very cold, so hot bottles were placed in the bed. During the night she slept fairly well but vomited twice after drinking a little milk. On the 16th the aspect of the child had completely altered during the past two days. She now lay in bed with her knees drawn up, taking no notice of anything, but answering when spoken to and complaining of great frontal headache and of pain in the abdomen; her eyes were very sunken and her face was somewhat pale, worn-looking, and drawn; in fact, her aspect resembled that of a patient who had suffered from some severe illness, such as typhoid fever, for some weeks. The child was very cold, her tongue was coated and dry, her pulse was quite feeble, very rapid and irregular; in fact, she was very ill. She had been given an enema simplex and was receiving bismuth mixture every four hours; she retained no food, vomiting immediately anything that she swallowed. It had been thought up to now that probably she was developing some intercurrent disease. However, her aspect and the continual vomiting made me suspect acid intoxication, so a sample of urine was obtained, which Dr. T. Houston kindly tested and found it to contain diacetic acid, thus confirming the diagnosis. She was now given rectal injections of 1 drachm of bicarbonate of sodium in 2 ounces of warm water every four hours, and during the night, also bismuth mixture and a little peptonised milk and water, this and the mixture containing 10 grains of bicarbonate of sodium to the dose, but both were vomited immediately after being drunk and so were stopped. On the 17th the child was distinctly better, the worn aspect had vanished, and the eyes did not appear so sunken. She looked brighter and felt easier and had no headache or pain in the abdomen; the pulse was still rapid but regular and better in quality. During the early part of the night she had vomited twice, but not since she was not given any food by the mouth, receiving rectal feeds of 4 ounces of peptonised milk containing 20 grains of bicarbonate of sodium every four hours. After 6 P.M. she was given peptonised milk in half-ounce quantities by the mouth which she retained. This was therefore gradually increased in quantity as no vomiting occurred, the rectal feeds being continued during the night. On the 18th there was no vomiting, the child looked brighter and better, and did not complain of pain anywhere. The pulse was slower, steadier, and improving in quality; the tongue was becoming clean. The rectal feeding was now discontinued, the patient being given 5 ounces of peptonised milk every two hours by the mouth; in the evening this was replaced by ordinary milk. On the 19th the child was improving rapidly; there was no vomiting and the pulse was normal. The urine tested on this day was found to be free from diacetic acid. The subsequent history was uneventful. The temperature during the illness never rose above 99·8° F., nor fell below normal.

This, then, appears to be a case of acid intoxication following ethyl-chloride anæsthesia, which when recognised and treated appropriately had a fortunate termination, though on the third day after the operation the little patient was so ill that this, coupled with the fatal terminations in the recorded cases following chloroform administration, made one give a very gloomy prognosis. In view of the able manner in which Mr. Campbell has described the whole subject of chloroform poisoning I will refer the reader to his paper and content myself by quoting as an explanation why acid intoxication should follow ethyl-chloride administration the suggestion made by Dr. V. G. L. Fielden, the anæsthetist to the hospital, that the halogen group occurs both in chloroform and in ethyl chloride. In conclusion, I have to thank Miss Tate, the matron, for many of the notes on this case.

Belfast.

A NOTE ON THE DEVELOPMENT OF SECONDARY NODULES IN SUTURE SCARS AFTER OPERATIONS FOR THE REMOVAL OF CANCER.

BY C. W. MANSELL MOULLIN, F.R.C.S. ENG.,
SENIOR SURGEON AND LECTURER ON SURGERY AT THE LONDON HOSPITAL.

IN THE LANCET of Nov. 9th, 1907, Mr. Charles Ryall called the attention of the profession to the very grave risk of cancer infection taking place during the performance of operations for the removal of cancerous growths, and instanced many cases in which it seemed to be obvious that such infection had occurred. One of the examples brought forward was the well-known frequent recurrence of the disease in the suture cicatrices after operations upon the breast, and several striking instances were mentioned in which infection had taken place around a laparotomy wound even when the operation had been merely of an exploratory character. A case that has been recently under my care illustrates this point well, but at the same time suggests that the mode of transference of the cancer infection is not of quite such a simple character as is usually believed. The sutures must bear a part of the blame, perhaps the greater part; but there is something more than the mere conveyance of a cancer cell from one spot to another by the needle or suture employed.

The patient, a man 48 years of age, was sent to me with the history that he had suffered from chronic gastric ulcer for the last 18 years, and that lately, in spite of medical treatment, the attacks of pain and vomiting had become more frequent. Cancer had supervened upon the old ulcer, as it so often does, and at the operation a tight stricture of the pylorus was found with some disseminated nodules scattered over the serous surface of the stomach. Posterior transmesocolic gastro-enterostomy was performed and the patient made an uneventful recovery. Six months later I saw him again. He was much better so far as pain was concerned and was considerably stouter, but there was a double row of cancer nodules on either side of the laparotomy wound. Two sets of sutures had been inserted: one, of stout catgut, interrupted, passing through all the layers of the abdominal wall except the skin; the other, of finer catgut, continuous, through the skin only. Practically all the suture points of the former series were infected; none of the latter. It was evident that cancer cells from the peritoneal cavity had invaded the wall wherever the parietal peritoneum had been pierced by a suture. The sutures had not carried the cancer germs in, for they had never been near the growth; but either by perforating the serous layer or by acting as irritants they had helped the development of the invading germs to such an extent that each point had become a cancer nodule. The immediate source of infection was in all probability the nodules noted on the serous coat of the stomach, which were constantly rubbing against the anterior abdominal wall. The line of the laparotomy incision itself seemed to be intact between the two rows of nodules.

The same explanation, it seems to me, is the more rational one in those cases in which cancer recurs at the suture points after operations for mammary carcinoma. It is not that the cancer germs are carried in by the needle or suture mechanically at the time of the operation and left to grow in the puncture made, but that they are more widely distributed in the surrounding tissue interstices than is apparent at the time, and only develop, or perhaps develop first, at those points where the resistance of the tissues is lowered by the presence of an irritant such as a suture.

That healthy tissues do possess some power of resistance to the growth of invading cancer germs is obvious. The distribution of cancer germs from a primary focus must begin at a very early date, but it is a long time before secondary said that as the anæsthetists had not the after treatment of operative cases they only to a slight extent realised what a troublesome complaint post-operative vomiting might be. He had been using a method, suggested by MacArthur, of giving the patient frequent drinks of pure cold water right up to the administration of the anæsthetic, and this method had been entirely successful in nine cases, partially successful in 19 cases, and had had no result in 12 cases, out of the 40 patients who had been treated in this way.—Mr. PRINGLE said that he had noticed when administering anæsthetics that the less the patient was cyanosed during the administration the less vomiting there was afterwards, so that it was important to let the patient breathe a certain amount of fresh air.—Dr. T. P. C. KIRKPATRICK said that with regard to the preparation of a patient he did not look on abstinence from food as of such importance as thorough purgation some time before the anæsthetic was administered. The patients who usually gave most trouble with post-operative vomiting were those who suffered from more or less chronic constipation. Occasionally after chloroform anæsthesia vomiting became so serious as to threaten the patient's life; but this was exceedingly rare after ether.—Dr. W. I. DE COURCY WHEELER said that he had tried the open method of administering ether and had found it very simple and the anæsthesia perfect. The patients never became cyanosed, but he had not had enough experience of the method to say whether the vomiting was less frequent. It was particularly suitable for old or fragile persons. Alcoholic patients who were difficult to anæsthetise with ether vomited less than others; if the anæsthesia was begun with chloroform and continued with ether the vomiting was far worse.—Sir THOMAS MYLES said that he himself had been under every anæsthetic known. He had always insisted on having a cup of tea before the operation, and he was well purged out. He had never vomited or had a fit of sickness. He was inclined to think that the sickness was due to something inherent in the patient.—Mr. TAYLOR said that it had been his habit to give morphine either immediately before the anæsthetic or before the patient left the table; less anæsthetic was then required and there was less vomiting.

Sir THOMAS MYLES read a short paper on a case of Exophthalmic Goitre which he believed to have been cured by a diet of milk obtained from thyroidectomised goats. The patient was a married woman, 25 years old, and the symptoms had been developing for more than a year. All the well-marked features of the disease were present and there had been a progressive loss of strength and colour. The goats were operated on by Professor Mettam of the Veterinary College and when, two days later, the little wound in the neck had healed the goats were sent to the patient who resided in the country. At the end of a month the improvement was very marked and at the present moment the enlargement of the thyroid was barely perceptible and the exophthalmos had disappeared. For the last few months the milk diet had been supplemented by the use of Merck's tablets and by the administration of small doses of iron and arsenic.—Mr. TAYLOR said that the method had been tried on the continent some years ago and a powder made from the milk of thyroidectomised goats could be bought, but the professors on the continent had not spoken much in its favour.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—The annual meeting of this society was held at Manchester on Jan. 17th.—Dr. A. J. Wallace (Liverpool) was elected President for 1908, and the other office-bearers were duly elected.—Dr. E. O. Croft (Leeds), the retiring President, gave a short valedictory address in which he discussed "The Woman of the Future from a Gynæcologist's Point of View," in the course of which he suggested picturing in mind a typical healthy woman in the more or less distant future, and estimating the probability of her enjoying an immunity from many of the physical and mental disaffections as known to the gynæcologist of the present day. The gynæcologist of that day would require the command of a much higher knowledge of prophylaxis and of the conditions of normal health, and such knowledge would have to become an integral part of his mental equipment. The indications of such a development were referred to and exemplified. Rapid advances were liable to be associated with exuberances of rapid growth and feeble vitality. These exuberances were temporary hindrances and were more liable to form in the process of mental than physical development. They chiefly appeared in the form of eccentricities of various kinds. The various classes of gynæcological disease were reviewed in the light of their ultimate avoidance. The large class of inflammatory affections which were mainly associated with microbial infection of varying degrees were to be looked upon as avoidable, as also were many of the diseases of pregnancy and abnormalities of labour. The eradication of the venereal infectious diseases was not being dealt with at all at the present day. It was to be hoped that a more common-sense view would be taken of the matter in a more enlightened future. The prevention of puerperal infection seemed to be a difficult lesson in spite of its simplicity. It was suggested that the ultimate solution of the question would be in the hands of the suffering women-kind. When they themselves fully realised the position they would demand the remedy, and the demand would be more quickly met. With regard to the possibility of dealing with the apparently hopeless conditions of mal-development, the suggestions of Dr. J. W. Ballantyne and the subject of eugenesis were referred to. There was no clue to the prophylaxis of the new growths of the female organs, such as cystic disease, fibroids, and cancer. Referring to fibroids, the brilliant results of a curative kind obtained by operation during recent years, while of enormous immediate value, had practically paralysed all research into the etiology and nature of these growths. More work was being done regarding cancer, but the high degree of technical skill required of the operator and the pathologist had rather tended to create a chasm between the two which was difficult to bridge. Both were liable to be lacking in the opportunity for the observation of the living habits and phenomena of the disease as it progressed in the patient.

HARVEIAN SOCIETY.—A meeting of this society was held on Jan. 23rd, Dr. G. A. Sutherland being in the chair.—The evening was devoted to the showing of clinical cases and pathological specimens. Dr. Sidney P. Phillips showed: 1. A case of Splenic Anæmia in a Child. The liver, spleen, and lymphatic glands were enlarged and the blood showed the usual signs of anæmia but no leucocytosis.—The case was discussed by Dr. Sutherland.—2. A case of Landry's Paralysis in which recovery had taken place.—Mr. W. H. Clayton-Greene showed: 1. A case in which Rupture of the Liver had occurred from abdominal injury. An operation was performed within seven hours of the accident and recovery followed. 2. A specimen of Cirsoid Aneurysm of the Arm and Forearm. The arm had been amputated owing to the extensive involvement of the vessels. This was discussed by Mr. V. W. Low.—Dr. Willcox showed: 1. A case of Greatly Enlarged Lymphatic Glands on Both Sides of the Neck which he regarded as due to lymphadenoma, with tuberculous infection superadded, the latter having been proved by investigations of the opsonic index. The case was discussed by Dr. Sutherland. 2. A case of Enlarged Liver and Spleen with Leucodermia. This was regarded as cirrhosis of the liver.—Dr. F. Langmead discussed the case.—Dr. Langmead showed a case of Third Nerve Paralysis, which was discussed by Dr. Sutherland.—Dr. D. W. Carmalt-Jones showed a case of Arteriosclerosis with a Vascular Lesion giving rise to a crossed sensory lesion.—Mr. Low showed a case of Charcot's Disease of the Knee-joint with spontaneous fracture of the tibia on the same side. There were well-marked signs of tabes dorsalis.—Mr. T. Crisp English showed: (1) A case of Charcot's Disease of the Ankle Joint, which was discussed by Mr. Kelly; and (2) a specimen of Large Fibroma of the Breast.—Mr. Lawrence Jones described (1) a case of Musculo Spiral Paralysis; and (2) a specimen of Ureteric Calculus.—Mr. S. Maynard Smith showed a case of Injury to the Brachial Plexus followed by a root paralysis which recovered after operation.—The case was discussed by Dr. Willcox.—Mr. E. Morris showed a skiagram of a Supernumerary Thumb.—Dr. C. Singer described the drawings, microscopical and pathological specimens, of a case of Exophthalmic Goitre which had recently been under his care.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on Jan. 22nd, Dr. W. Hunter being in the chair.—Dr. C. H. Cattle and Dr. J. R. Edward showed a man, aged 35 years, who had made a good recovery after operation and drainage of an Abscess of the Lung in the Left Infra-scapular Region. The exact mode of origin of the condition was uncertain but it was most probably a sequela of pleuro-pneumonia. Although he at one time expectorated from 12 to 18 ounces of pus per diem was of congenital origin, the symptoms dating back as they do to the early age of three years. An alternative supposition is that the primary condition was renal calculus with impaction of the calculus in the upper end of the ureter and hydronephrosis; subsequent infection would lead to pyonephrosis, ulceration around the calculus would cause it to be loosened and drop back into the dilated pelvis (no stone was ever known to be passed), and the healing of the ulcer would bring about cicatricial contraction of the uretero-pelvic junction.

Manchester.

SEVERE SPASMODIC CONTRACTION OF A FINGER CURED BY STRETCHING THE MEDIAN NERVE.

BY JAMES ADAMS, M.D. ABERD., F.R.C.S. ENG.

A WOMAN, aged 45 years, a widow who earned her living by needlework, came under my observation in November, 1905, for extreme contraction of the middle finger of the right hand. She gave the following history. In December, 1902, she pricked the thumb of her left hand and it became swollen, tender, and inflamed, and it suppurated. As it did not improve but on the contrary got much worse she went to University College Hospital, London, in January, 1903, and remained there for two months, all the fingers and hand becoming involved in what was evidently a septic infection. The fingers and hand were freely incised and drained and the patient was discharged in March with drainage-tubes still in. She returned to the hospital in the following May with the wounds unhealed and the mischief spreading further and amputation was performed at the middle of the forearm. The surgical registrar of the hospital, Mr. O. L. Addison, has sent me the report of her case. He says: "The patient was admitted to University College Hospital with a septic infection of the palmar sheaths and cellulitis of forearm following a poisoned wound of the thumb. The arm had to be amputated to prevent further extension of the suppuration."

In February, 1905, the middle finger of the right hand began to contract, and in November the patient was admitted under me to the union infirmary with the finger badly contracted. There were no signs of disease in the finger. With much force and some difficulty I could extend the finger fully but it gave her great pain to allow me to do it and when freed the finger at once returned to its state of rigid contraction with the tip firmly fixed in the palm. Before admission the finger had been treated in various ways without success and after admission I tried internally anti-rheumatic and anti-gouty medicines and iodide of potassium in large doses; also locally I ordered hot brine baths, liniments, ointments, massage, &c., as well as applying splints to the palmar surface by which I could keep the finger extended, but all without the least benefit. It was very painful to the patient to have it kept in a position of complete extension and it also proved useless, for when the splint was removed the finger at once re-contracted. After six weeks' treatment with no result the patient begged me to amputate the finger as it was so inconvenient to her, besides preventing her from earning her living. Accordingly, in January, 1906, I removed the finger at the metatarso-phalangeal joint with the head of the metatarsal bone. The wound healed normally and quickly and in February she returned home to her work with a useful hand and with the rest of the fingers in a normal condition.

For six months this continued, but in August the ring finger began to contract and in spite of treatment became as bad as the middle finger had been, and in November she was readmitted in order to have this finger also amputated. The condition, appearance, and symptoms were identical with those of the other finger. It was in a state of marked tonic contraction with its tip fixed and kept firmly in the palm. By no effort on her part could she move it, and I could only extend it by using much force and giving her great pain; on my releasing it the finger returned at once to its vicious position like a strong spring set free. The finger was not swollen, red, or painful, and its sensation was normal, and the other fingers were normal in every way, as were the hand, the forearm, and the upper arm. The patient's general health was excellent, her appetite was good, and she slept well. She is a placid, non-neurotic type of woman, dark complexioned, well nourished, and is active and industrious.

To remove a second finger from the hand of a woman of this class, already deprived of her other hand, would be indeed a serious misfortune for her. Instead of again putting her through a course of treatment I showed her at a meeting of the Eastbourne Medical Society, where she was examined thoroughly and with much interest by about 20 members who were present. A suggestion was made that stretching the median nerve might be beneficial and I readily acquiesced in this, for I was very reluctant to amputate. In December, 1906, I operated. I cut down at the junction of the middle and lower third of the upper arm, making a three-inch incision in the course of the nerve, and at once came on it lying in its normal situation. I separated it from its bed, took it up with my forefinger and thumb, and stretched the distal portion forcibly for four or five minutes, and then the proximal end for the same time. The wound healed kindly and the operation was simple and easy, taking only a short time to do. While under the anæsthetic the finger could be readily extended as was the case in a patient of Professor Nussbaum to whom I shall again refer. Before my patient had recovered from her anæsthesia I put the finger on a palmar splint and kept this up for three weeks, removing it twice a day for passive exercise. At the end of this time I ordered the splint to be kept on by night only for another fortnight and then left it off altogether. For nearly a month the patient had numbness in some of the fingers and disordered sensation in parts of the hand, and, curious to relate, the numbness was in the two fingers supplied by the ulnar nerve—viz., the little and ring fingers—there being no numbness in the thumb and forefinger. Brown-Séquard refers to a similar occurrence as regards sensation when on stretching the sciatic nerve in guinea-pigs the part of the foot innervated by the anterior crural nerve became anæsthetic and sometimes even the leg on the opposite side to that of the operation became also anæsthetic. In one case there were an incomplete paralysis and anæsthesia in the right leg after considerable stretching of the sciatic nerve on the left side. And he adds: "It is clear that the spinal cord is modified by the stretching of a nerve" (Holmes's "System of Surgery," Vol. II.). After leaving off the splint there was no contraction of the finger or tendency to contraction, and three months after the operation I had the satisfaction of showing the case again to the local medical society with the finger cured and the patient possessing a useful hand.

In December, 1907, the patient came to see me and she could bend and extend the finger normally and there was no tendency to contraction; and as a year has elapsed since I stretched the nerve the cure may be regarded as permanent.

The etiology of the case is obscure and I can only state its negative side. It was not a Dupuytren's contraction nor an osteo-arthritic finger, neither was it inflammatory nor a sequel of inflammation, nor gout, nor rheumatism, nor an example of neuromimesis. The tissues and joints of the finger I amputated were all healthy. The contraction was certainly not organic but was a true spasm and became more violent the more that one attempted to oppose it.

I can find no instance of stretching the median nerve having been done in England for contraction of a finger. Callender relates a case of stretching it for neuralgia, and Morton for athetosis, in which both median and ulnar nerves were stretched with success. The nearest case to mine which I have been able to find is that by Professor Nussbaum. He describes operating on a tuberculous girl, six years of age, in which in the course of a resection of the elbow for ankylosis at an inconvenient angle some traction was exercised upon the ulnar nerve and a spasmodic contraction of the fourth and fifth fingers which had hitherto existed was in consequence completely cured. Professor Nussbaum relates at length in the same article a successful result of stretching the ulnar nerve, and the various branches of the brachial plexus in the axilla for extreme spasmodic contraction of the hand, forearm, and upper arm accompanied by anæsthesia of dorsal aspect of the forearm in a soldier, aged 23 years, the condition being the result of traumatism. In this patient, as in mine, under an anæsthetic all spasmodic action ceased.

Had I stretched the nerve when the patient first came under my treatment I have no doubt that I should have saved the middle finger from amputation, as I have now done the ring finger. No doubt the rarity of such a form of spasmodic contraction in a finger partly accounts for the rarity of the

the surgery of insanity, and Dr. Woolsey on the surgery of the spine; the subjects are treated very satisfactorily.

Where all are so good it is a little invidious perhaps to single out any individual article for special praise: but we may perhaps mention that we think Dr. Eisendrath's paper on fractures is especially good.

Handbuch der Gynäkologie. By Various Authors. Edited by J. VEIT. Second revised edition. With numerous illustrations. Vol. I., pp. 836. Wiesbaden: J. F. Bergmann. 1907. Price M.16.60, or 16*s.* 9*d.*

SINCE the first edition of this work appeared four of the contributors have unfortunately died—namely, Gebbard, Gessner, Löhlein, and Viertel—and for this edition their places have been taken by Fritsch, Frommel, Nagel, and Winternitz. This volume deals with the prevention of infection in gynæcology, displacements of the uterus, and fibromyomata of that organ. The first section, on the prevention of infection, is written by K. Franz of Jena. For the disinfection of the hands he recommends a modification of Fürbringer's method and the use of rubber gloves. The risk of infection *from the skin of the patient during the* operation is prevented by covering the patient entirely with a sterile covering to an opening in which the edges of the incision in the skin are fastened by clip forceps. Catgut sterilised by cumol is recommended as an ideal suture material whenever it can be used.

The article on the normal and abnormal positions of the uterus is contributed by Otto Küstner of Breslau. It contains a very complete account of the symptoms and treatment of all the displacements of the uterus, especially the operative treatment of prolapse of that organ. The coloured drawings depicting the various stages of different operations are exceedingly good, as are also the numerous drawings of sections of the pelvis in the different stages of prolapse of the uterus. R. Meyer of Berlin discusses the anatomy and origin of myomata and fibromata of the uterus. The author apparently favours Ribbert's theory of the origin of fibromyomata from young muscle cells embryonic in character in so far as they are young, and he states that all grades of development can be traced between such young muscle cells and the cells composing small growing fibroid tumours. The important question as to the mode of origin of adenomyomata of the uterus is very fully considered. The etiology, symptoms, diagnosis, and prognosis of these tumours are considered by the editor who also describes the palliative treatment and the operative treatment of such growths when undertaken by the vagina. The electrical treatment is described shortly by R. Schaeffer of Berlin.

The last two sections, the most valuable in the work, are contributed by R. Olshausen of Berlin and deal with the various abdominal operations which may be performed for uterine fibromata and the diagnosis and treatment of pregnancy when complicated by the presence of such growths. The relative value of the different modes of carrying out the abdominal operations is discussed in detail, and the conclusion is come to that abdominal supravaginal amputation is as a rule preferable to the operation of total hysterectomy in these cases. To anyone who wishes to read a judicious and able account of the risks which a patient may or may not run with a pregnancy in a uterus containing fibroid tumours we can strongly recommend this last article in the volume. The author's immense experience enables him to point out very clearly the important problems involved in the treatment of these cases.

This second edition well maintains the high standard of merit attained by the first and this volume is a very valuable addition to the German literature on gynæcology.

LIBRARY TABLE.

A Text-book of Clinical Anatomy for Students and Practitioners. By DANIEL N. EISENDRATH, A.B., M.D., Adjunct Professor of Surgery in the Medical Department of the University of Illinois; attending Surgeon to the Cook County Hospital, Chicago. Second edition. London and Philadelphia: W. B. Saunders Company. 1907. Pp. 535. Price 21*s.* net.—This second edition of Dr. Eisendrath's Clinical Anatomy is said to have been "thoroughly revised" but we regret to find that mistakes are still numerous. The illustrations, though beautifully executed, are in several instances technically incorrect; for example, on p. 175, the commencement of the inferior vena cava is represented as taking place to the left of, and almost on a level with, the umbilicus; next, on p. 185, only three synovial sheaths are allotted to the extensor tendons of the wrist and fingers, whereas there ought to be six, while one of the compartments is labelled as being the "common tendon-sheath of the extensors of the middle, ring, and little fingers." Again, Fig. 37, p. 121, showing "surface markings of principal structures of neck *and of thorax in child," is, we consider, valueless, for the* outline of the sternum, the ribs, and the clavicle is omitted, the ascending aorta is placed too far to the left, and the innominate artery is twice as long as it ought to be. In the section on the Abdomen there are again some errors. The union of the cystic and hepatic ducts does not take place near the lower border of the first part of the duodenum, as shown in Fig. 73, and the duodeno-jejunal flexure is not usually situated below the lower pole of the left kidney, as appears in Fig. 69. The book is well bound and printed on good paper but in our opinion is still in need of revision.

The Office of Midwife (in England and Wales) under the Midwives Act, 1902. By STANLEY B. ATKINSON, M.A., LL.M. Cantab., M.B., B.Sc. Lond., of the Inner Temple, Barrister-at-Law. London: Baillière, Tindall, and Cox. 1907. Pp. 123. Price 3*s.* 6*d.* net.—Dr. Atkinson has done a considerable service to all those interested in the working of the Midwives Act, 1902, in writing this little book. He has gathered a large amount of very useful and interesting information. In the first part he traces the evolution of the midwife from the period when women were licensed by the bishops or their chancellors to practise midwifery, up to the time of the institution of the Central Midwives Board. He informs us that Bishop Bonner in the year 1554 is supposed first to have granted these licences. The explanation given of this early ecclesiastical control is the necessary presence of the midwife at what is the first and not infrequently the last breath of human life. Midwives were instructed carefully by the clergy as to the necessity, the manner, and the exact words of emergency infant baptism. The author gives a most interesting review embracing the evolution not only of the midwife but also that of the man-midwife, the early development of lying-in hospitals, and the progress of midwifery in the nineteenth century. It will no doubt be a matter of surprise to those medical men who have no special knowledge of the subject to learn that it was only as late as the year 1852 that the Royal College of Surgeons of England obtained a supplementary charter enabling it to examine "persons" for a diploma, Licentiate in Midwifery of the Royal College of Surgeons of England, and it was not until the Medical Act, 1886, Section 2, became law that a triple qualification in medicine, surgery, and midwifery was essential before the registration could take place of the would-be medical practitioner. In Chapter II., on the Prospects and Present Position of Midwives, Dr. Atkinson points out how few midwives are likely to be left in practice in some parts of the country if the local supervising authorities strictly put into force the powers conferred femur had been broken by a simple fall in April; splints were removed three weeks later on account of *extensive swelling of the thigh which was said to have* reached three times the size of the opposite one; there had been some diminution in size, but at the time of operation, in November, 1901, it still measured 15 inches in circumference, twice the size of the opposite limb at a corresponding point. *Examination with the x rays appeared to* confirm the diagnosis of osteo-sarcoma. It was the only growth to be found on the skeleton and his general health was satisfactory. Amputation at the hip was followed by a good and rapid recovery. The family history was good at that time, but a *few months later his mother underwent* amputation of the thigh for osteo-chondroma of the femur, while another child, a boy, aged three years, is now (January, 1908) in a hospital with a growth of his femur following a fracture; from the account given the case is a similar one. On June 9th, 1903, *the subject of the* communication was again taken to the hospital for a growth of smaller size affecting the lower end of the right femur; this presented characters similar to those of the original growth but did not prevent his getting about. When again admitted to hospital in March, 1907, *the growth of* the right femur had disappeared, leaving no trace. There was, however, a tumour of the tibia present which dated from an injury 12 months before, due to a fall on the pavement. An incision had been made into this (the scar of which remained) and a diagnosis of *sarcoma given. The* tumour had diminished in size and there had been less pain afterwards. There had been a change also in the appearance of the head, which was enlarged and bossy, due to a thickening of the outer table. There were also small bony growths of the ulnar bones in no way resembling the characters of inflammation or of sarcoma. By means of the x rays the tumour of the tibia could be clearly defined, and although the outline of the tibia could be distinctly traced through it, it was not invaded by the growth, which was distinctly circumscribed and of bony structure, resembling an osteoma. After giving the account of the case Mr. Battle and the President made reference to the various conditions which might cause a difficulty in the diagnosis of tumours of the long bones following injury, the chief difficulty being met with when there was a resemblance to periosteal *sarcoma*. A case of traumatic subperiosteal hæmatoma in which there had been a development of bone which gave egg-shell crackling on manipulation was *related, the specimen* being in the museum of St. Thomas's Hospital. The femur was the bone affected and amputation had been done at another hospital *on the supposition* that the case was one of hæmorrhagic sarcoma. There was a history of improper feeding. Reference was made to cases published in a lecture by one of the readers of the paper (Mr. Battle) which appeared, with illustrations, in The Lancet of August 27th, 1904, p. 580. *In that lecture* examples were given of excessive formation of callus after fracture when too much *movement of the* fractured ends had been permitted *or when the* patient was the subject of locomotor ataxy. A case now under observation of a similar condition following fracture in a man the subject *of general* paralysis of the insane was also adduced. The characters of the tumour produced in a long bone which was affected by osteitis deformans confined *to that* bone were pointed out. The great difficulty sometimes experienced in making a diagnosis in necrosis, if the sequestrum was small and the *x rays* failed to *show* it, was drawn attention to, whilst, finally, allusion was made to the well-known case of leontiasis ossea in which the fibula was *occupied* in part by a large bony mass similar to that which *affected* the head and face bones. A case of localised enlargement of bone reported by Mr. Bilton Pollard *was also* mentioned. Finally, the great difference between the tumours which appeared in this case and the varieties of cancellous osteomata was pointed out, it being considered that from a clinical point of view the growths which formed the subject of this communication constituted a distinct and separate *type*. To the naked eye the tumour consisted of a finely cancellous osseous tissue, the interstices of which were filled with adipose medulla. In the latter there were strands of proper medullary tissue comprising finely and coarsely granular myelocytes, lymphocytes, and *erythrocytes. No* histological *marks of inflammation* were present and the growth must be classed as a cancellous osteoma. Mr. Bilton Pollard had described under the title of "hypertrophied callus of the tibia and fibula" a *fusiform* formation which followed an injury. The limb was amputated on the supposition that the disease was sarcomatous. In this case, *however, the original bone was replaced by the new formation*, and the interstices of the cancelli were occupied with cellular connective tissue, without a trace of fat or proper marrow; the lesion for this reason did not bear classifying as a cancellous osteoma but was rather an *inflammatory or irritative hyperostosis. The tumour* on the femur of the child's mother fell histologically into Virchow's group of osteoid chondroma. The growth of osteomata in her two children became thus an example of the heredity of benign tumours, which in the case of chondromata *and osteomata was so striking and well established.* A further matter of interest in the history of the boy was that bony tumours afterwards grew around other bones and that one of these disappeared spontaneously. That around the tibia appeared after an injury. The only comparable case in *this regard* of which Mr. *Battle* and the *President* knew was one recorded by Abernethy in which osseous formations ensued after local injuries, some of which formations spontaneously disappeared.

Dr. W. O. Meek read a paper on "Tuberculous Endo*carditis*" based on a pathological examination of two cases of miliary tuberculosis.

Dr. H. A. Colwell showed some photographic plates which had been placed in contact with sections of vesical calculi in the dark. After development a more or less *faithful* picture of the calculus was in the majority of cases obtained, which, however, showed that the action upon the silver salt was confined to certain strata of the calculi. Thus the nucleus, which consisted in each case *of comparatively* pure uric acid and was compact in character, *produced* no photographic effect. On the other hand, layers of calculi, which were of more porous consistency and which also consisted of uric acid in combination as well as uric acid itself, gave positive results. Phosphatic *portions of the* calculi were without effect except when mixed with urates. The external layers of a *predynastic* Egyptian calculus lent by the President from the collection of the Royal College of Surgeons of England also gave a positive result, the nucleus being without any apparent effect.

Mr. Cecil W. Rowntree read a paper on a case of Malignant Disease *of the Rectum* in a boy, aged ten years.

Mr. Walter G. Spencer showed a case of Chimney-sweep Carcinoma.

MEDICAL SOCIETY OF LONDON.

The Use of Chemicals in Aseptic Surgery.—Nervous Phenomena in Pneumonia.

A meeting of this society was held on Jan. 27th, Dr. J. Kingston Fowler, the President, being in the chair.

Mr. C. B. Lockwood read a paper on the Use of Chemicals in Aseptic Surgery. He said that at the present time attempts were being made to conduct surgery without the use of chemicals, but there were many surgeons, himself among the number, who still used chemicals. Whatever means surgeons adopted the aim was the same—namely, to banish bacteria from the field of operation, from everything brought in contact with the wound, and from the wound itself. Nothing short of that would ever content him. As far as possible heat was used by everyone to kill bacteria and when heat could be properly applied its effects were asepsis. A long series of tests performed regularly for 15 years led to the conclusion that bacteria seldom reached wounds from anything to which heat could be properly applied. Wound infection came from the hands and person of the surgeon and his *assistants, from* the skin of the patient, and from the atmosphere. Mr. Lockwood said he used what was commonly known as spirit and biniodide of mercury lotion which was more correctly described as a solution of mercuric iodide in iodide of potassium. Alcohol was a powerful germicide and had the *additional* advantage of penetrating and removing the cutaneous grease. His method was to cleanse the hands in the usual way, soak them for not less than two minutes in spirit and biniodide lotion, and transfer them repeatedly from that lotion into a watery solution of biniodide of mercury 1 in 2000. *The effect* was to cause the biniodide to enter into a close alliance with the skin but not into chemical combination with it. It could be demonstrated that the skin contained an appreciable quantity of mercuric iodide after this method had been used. The plan, however, required care, accuracy, and publication is a worthy product of the *entente cordiale* which binds together all nations in the world of science. Dr. Osler's Text-book of Medicine is probably known to most of our readers and as we have reviewed it through six editions there is no need to allude at present to the matter of the book but only to the manner of its presentation. We may say, in a word, that Dr. Osler's work lends itself to translation admirably, and has been admirably translated. Indeed, many French students might read it and were it not for the title-page think it to be a French treatise. This we suspect to be due to Dr. Osler's exceptional knowledge of pure English and ability to say exactly what he means in plain and well-balanced phrases which leave his translators no doubt of their only possible counterpart in French. The result is that the translation is almost literal and the success of the work from a French point of view is made greater by the clear manner in which the author arranges his sections, which entirely agrees with the French method of teaching. Dr. Marie in a little prefatory eulogy of Dr. Osler refers to him as "né au Canada, et par conséquent de nationalité anglaise"; possibly "nationalité britannique" would be a more acceptable term to many of our fellow-subjects. English students might do well to buy their text-book in this French form, as it would improve both their medicine and their French, and we can assure them that medical works written in that language afford the easiest French that a medical man can find to read.

JOURNALS AND MAGAZINES.

The Annals of Tropical Medicine and Parasitology. Vol. I., No. 3. November, 1907. London: Williams and Norgate. Liverpool: At the University Press. Pp. 207, illustrated. Price 7*s.* 6*d.* The first paper in the present number is a continuation of the communication Concerning Certain Parasite Protozoa observed in Africa, by the late J. Everett Dutton, M.B. Vict., John L. Todd, B.A., M.D. McGill, and E. N. Tobey, A.B., A.M., M.D. Harvard. It deals with parasitic protozoa found in some other mammals than those described in the first part of this communication, with others found in birds, reptiles, fishes, amphibia, and in arthropoda. Although these parasites are not apparently connected with any disease occurring in man and the descriptions are in themselves more or less incomplete and disconnected, the recording of the observations made will probably prove of considerable value in the future. It may well be that some of these parasites may be found to live in the human body. At any rate, facts connected with the life-history of this class of parasites in animals other than man will very probably serve as a guide in the study of human parasites. The matter contained in the communication, however, is of such a technical and specialised nature that it would be out of place to deal with it here at any length. Dr. C. W. Branch of St. Vincent contributes a valuable and interesting paper on Yaws in the West Indies. Dr. Branch, who has had a wide experience of the disease, is definitely inclined to the view expressed by Mr. Jonathan Hutchinson that "yaws" is identical with "syphilis." He admits, however, of some doubt on this point. His attitude is more or less completely expressed in the following passage: "If 'yaws' is not 'syphilis' then there is still abundant indication that the treatment is the same and we should insist on the early and persevering use of mercury; for the time for treatment of 'syphilis' is in the early secondary stage, and by inference the same must be true of 'yaws.'" Dr. Branch criticises adversely what Sir P. Manson says with regard to "yaws." Sir P. Manson stated that the primary sore, the affection of the fœtus, the adenitis, the exanthem, the alopecia, the absence of itching, the iritis, the affection of the permanent teeth, the bone and eye affections, the congenital lesions, the polymorphism of the eruption, the nerve lesions, and the gummata of "syphilis" are all wanting in "yaws." Dr. Branch states definitely that there is no doubt whatever about the occurrence of the primary sore. He is equally conclusive in his contradiction of all the other points with some slight exceptions, which he attributes to the difference in susceptibility between black and white races of men. He deals exhaustively with the "frambœsial" eruption and he brings much evidence and many arguments to show that this is identical with the papillomata, condylomata, and rhagades of "syphilis" Dr. Anton Breinl contributes a short note on the morphology and Life-History of Spirochæta duttoni. Dr. Breinl's conclusion is that just before the crisis of the disease the spirochætæ seem to disintegrate, several of them coiling up into skeins, the majority of which are distributed in the spleen. Some of them become encysted and break up into several small bodies, out of which the new generation of spirochæta is evolved. The first part of a communication on the Cytology of the Trypanosomes, by Professor J. E. Salvin-Moore and Dr. Breinl, forms the last article in this number of the Annals. A preliminary account of the observations relating to the Trypanosoma gambiense contained in the present paper was published in THE LANCET of May 4th, 1907, p. 1219. In the Annals a more exhaustive account of the morphology and life cycle of Trypansoma gambiense is given and Trypanosoma brucei and Trypanosoma equinum are also dealt with. The paper is very fully illustrated. Among other things, the authors suggest very strongly that the life cycle of Trypanosoma gambiense at any rate is complete in one host only and is in no way dependent for its completion upon the transference of the parasites into the blood of any other host. It would seem, in fact, that the transference by flies in the case of sleeping sickness may have no more significance with respect to the life cycle of the parasites than in the case of the transference of dourine from horse to horse by means of flies. The transference of sleeping sickness in fact when it is brought about by flies is in the nature of a direct inoculation of blood, and this inoculation might well be, and probably is, brought about by other means as well as by flies.

IN the *British Journal of Dermatology* for November, 1907, Dr. J. D. Rolleston makes an interesting communication upon Herpes Facialis in Diphtheria. His observations were based upon 1370 cases of that disease which had been verified bacteriologically, and of these 4·2 per cent. developed herpes on the face. In the great majority of cases it was labial but the cheeks, chin, and nostril were occasionally attacked. The sexes were about equally affected and its incidence increased in frequency until the twentieth year. It was always an early symptom and was not definitely related to the same side of the face as that on which the diphtheritic process was present in the fauces. In Dr. Rolleston's experience it is more likely to occur in the more severe cases, although Oral regards it as a favourable sign. Dr. Rolleston agrees that it occurs more frequently in non-diphtheritic angina than in diphtheria, as he has observed it in 13·1 per cent. of the former class of case, which comprised quinsy, Vincent's angina, and herpes of the fauces.

The West London Medical Journal.—The most important of the original communications in the January number of this periodical is perhaps that by Mr. W. Sampson Handley on Chronic Appendicitis in Women. The author points out that this condition differs from acute appendicitis in that the peritoneum is not affected and is of opinion that it is a frequent cause of right-sided "ovarian" pain in women. Dr. J. A. Mansell Moullin writes on Uterine Fibroids and apparently holds that operation is called for in all cases; and Dr. Samuel West contributes *a clinical lecture on Pericardial* not a point of great practical import. Dr. Sharp said he believed that ergotoxine was the one active alkaloid contained in ergot, although Dale believed that it had not the action on the heart that was attributed to crude ergot nor did it produce convulsions as did ergot. It produced all the other actions at least of ergot, including gangrene. The adult dose was $\frac{1}{100}$th or $\frac{1}{50}$th grain (0·0006 or 0·0012 gramme) for a single injection, or $\frac{1}{12}$th to $\frac{1}{6}$th grain (5 to 10 milligrammes) in the 24 hours. In small doses there is a rise of blood pressure, while after very large doses there is a fall with dilatation of the peripheral vessels just as with the rise in pressure there is constriction of the same vessels. This paralysis affects the junctions of the motor fibres of the sympathetic with the muscles—the so-called myoneural junctions. In fact, with large doses ergot and ergotoxine paralysed the very parts which adrenal stimulates. This fact had been seized upon and it had been practically employed by Dale in the standardisation of ergot preparations. The action of ergot and ergotoxine being on non-striped involuntary or plain muscle its effect could be well observed on the uterus. The action was both direct on the muscle and indirect through the sympathetic. In small doses it stimulated and contracted; in large doses it paralysed and inhibited or relaxed. This paralytic action was alone through the sympathetic. The muscle fibres suffered no paralysis, neither did the cerebro-spinal nerves supplying the uterus. It was now known that both effects depended on one alkaloid—namely, ergotoxine, and it was only a question of dosage. It was important from a practical standpoint to remember that after paralysis through the sympathetic the uterus still readily responded to mechanical or electrical stimulation. Dr. Sharp said that the alkaloid was the best preparation to employ when it was necessary to raise the blood pressure rapidly. In all other cases the liquid extract was preferable. He said that he had found it to be quite active at the end of 12 months. The dose generally given was too large. The limit of single doses to cause uterine contraction in connexion with labour was half a fluid drachm. The benefits of ergot were indirect rather than direct, for when the drug was given to expel foreign bodies from the uterus the tonic contractions which it set up might by expelling these put the uterus in the best condition in which nature could repair the damage done. In Addison's disease, in neurasthenia, in chilblains, in nervous disease, or wherever the vascular tone was wanting, ergot in small doses might do good indirectly by improving the tone. In regard to strophanthus, squill, and digitalis Dr. Sharp said that his own experience confirmed that of Dixon and Haynes that many preparations of strophanthus were below the standard but he disagreed with them as to the relative toxicity of the three drugs. Strophanthus when given under the skin was much more toxic than when administered by the mouth, but squill and digitalis were not so suitable for hypodermic injection, hence they could not draw parallel conclusions. Strophanthus was not an indirect diuretic like digitalis. Its diuretic action was direct but uncertain. It might relieve dyspnœa of cardiac origin. Squill was a good adjunct to digitalis but it was not of itself a heart remedy of great value. Digitalis he regarded as the only real heart tonic. He had shown that the tincture remained active for at least 13 months. When the pressure was very low, as in cases of extensive dropsy, it acted more rapidly than was generally believed. In one case he had known it to act in nine hours and in other cases from 12 to 16 hours, setting up active diuresis.

Dr. O. C. Gruner read a paper on Medical Student Life at Montpellier in the Middle Ages. The paper was illustrated by a number of lantern slides prepared from old drawings. The aspect of the city was first described with some minuteness and emphasis was laid on the clerical character of the university. Illustrations of the teaching of students, including one of a necropsy and some of out-patient diseases, were shown and a short account of this class of teaching was given. The clinical teaching of this University was that which made it famous. After reviewing some of the social conditions and illustrating the domestic side of medical student life an account was given of the ceremony of conferring of degrees. Quotations from an actual speech were given to illustrate the religious character of the degree ceremony in those days.

Mr. R. Lawford Knaggs read a paper on Angulation of the Sigmoid Flexure.

Mr. H. de C. Woodcock showed three cases with Calmette's Ophthalmo-reaction. He said that in 100 cases he had found that a positive reaction is not necessarily found in severe tuberculous infection. Also the reaction was present in some people not considered tuberculous, in people in full work and without illness. He had tried the inoculation of a blistered surface; it had answered very well and he was satisfied with it. He had not heard of its use anywhere but at Armley Hospital. He showed a chart demonstrating the great value of cryogenin in the high temperature of pulmonary tuberculosis.

Mr. J. F. Dobson showed a short and thickened Appendix, showing a Diverticulum at its Base, removed from a man who had had two attacks of appendicitis. A tag of omentum was adherent to the diverticulum.

Dr. T. Churton and Mr. H. Littlewood showed a case of Stenosis of the Œsophagus in a child, with skiagram by Dr. L. A. Rowden.

Dr. A. D. Sharp showed a patient with a Simple Neoplasm in the region of the left vocal process, right lateral pharyngitis, and marked hypertrophy of the lingual tonsil.

Dr. A. L. Whitehead showed an Eyeball excised for growth from a case in which Calmette's tuberculin serum test gave a positive result and the opsonic index was subnormal.

Dr. T. Wardrop Griffith showed a Heart from a patient who had been under his observation for 12 weeks prior to his death. At the necropsy very extensive vegetative endocarditis had been found affecting the aortic segments, leading to obstruction at the orifice, to insufficiency of the valve, and to aneurysm of the sinus of Valsalva.

Dr. Allan showed: (1) A Heart much hypertrophied and dilated showing a bulging of the wall of the left ventricle due to a growth in the wall, probably gummatous; and (2) the Right Lung of an infant, aged eight months, showing several cavities in the apex.

Mr. H. Wales showed an Anencephalic Monster.

Dr. E. F. Trevelyan showed a case of probable quiescence of an Intracranial Tumour occurring in a lad, aged 18 years. Six months previously he had suffered from severe headache, vomiting, and ocular paralysis. The general symptoms had entirely subsided but the eye symptoms still persisted.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Surgery.

Grafting of the Fibula to the Tibia.—Post-anæsthetic Vomiting.—Exophthalmic Goitre.

A meeting of this section was held on Jan. 17th, Mr. Seton S. Pringle being in the chair.

Mr. R. Atkinson Stoney read notes of a case in which he had Grafted the Fibula to the Tibia. The patient, a boy, aged seven years, was admitted to the Royal City of Dublin Hospital on Nov. 26th, 1905, suffering from acute osteomyelitis of the tibia; he had been ill for ten days and a huge abscess had formed involving the whole of the leg from the knee to the ankle. The abscess was opened immediately and the diaphysis of the tibia was found to be completely stripped of its periosteum. The necrosed tibia was removed by two operations, in January and in April. By April, 1906, the sinuses had closed and an involucrum had formed in the lower and upper parts of the leg, but there was a gap of about one and a half inches between the two ends, due to destruction of the periosteum, as the result of the virulence of the original infection. An operation was performed in which the neck of the fibula was cut across and the upper end of the lower fragment was implanted into the upper end of the involucrum of the tibia. Firm union had now occurred and the boy was able to run about without the aid of a stick, though there was considerable shortening as the result of over a year's loss of growth while the illness lasted and the ends of the tibia were not in contact. The operation was a modification of one described by Hahn in 1885, and was suggested by a case reported by Professor E. E. Goldmann of Freiburg in The Lancet of Jan. 13th, 1906, p. 82. There was no tendency of the ankle to turn outwards.—Mr. Pringle said that the case was, so far as he knew, the first of the kind reported in Ireland, or at any rate shown at the Academy. He believed it was the only line of treatment which was likely in such a case to leave a useful limb.

Dr. Gunn read a paper on Post-anæsthetic Vomiting. He patient is sitting, K when the patient is in the dorsal or lateral decubitus, while the dummy cup L receives the screw-plug M when D and K are in use. These funnels are guarded by fine meshed metal diaphragms to prevent glass dust entering when the tube breaker is employed. Fig. 3 shows the cylinder which is used when N_2O is to be administered. It is provided with three-way valves. The lever B being at *0* air is respired; at *4* the inspiratory and expiratory valves C and A are put into action; when turned further to-and-fro breathing is allowed. The gas is admitted through the tap at the distal end of the bag. When ethyl chloride is to be used concurrently with N_2O the sponge-holder G is inserted and the anæsthetic is introduced through D or K. For the N_2O and ether sequence anæsthesia can be induced as above and then the N_2O cylinder exchanged for the general anæsthetic cylinder or, what is simpler, the last-named can be used throughout, to-and-fro breathing being allowed from the outset. The ether attachment shown in Fig. 4 is extremely ingenious and easily controlled. It is screwed into K and on turning the screw V the ether passes down and wets the sponge. The receiver is fed by apertures controlled by Z. It is made of metal and glass so that the ether is always in view.

FIG. 2.

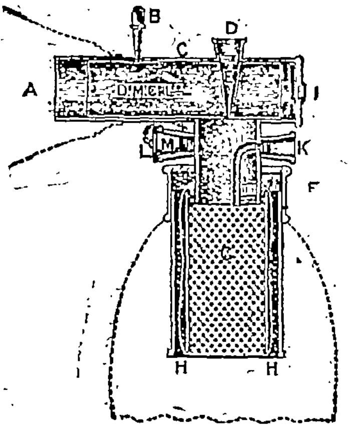

FIG. 3.

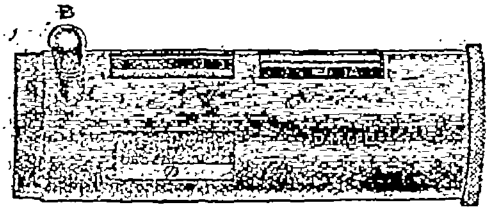

FIG. 4.

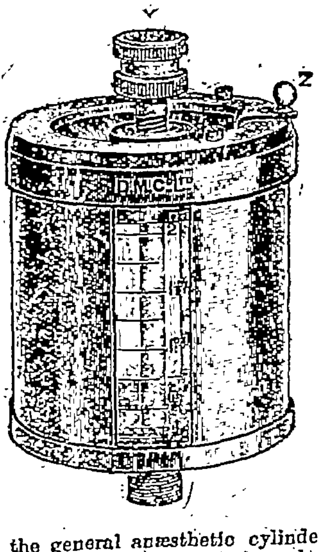


It is suggested by the inventor that for chloroform and its mixtures the anæsthetic should be placed in this receiver and be allowed to pass drop by drop at any desired rate upon the sponge; when so used the bag must be detached. It is to be pointed out that no breath contamination takes place, so that there need be no waste by anæsthetic residues. Mr. Vernon Knowles has modified Dr. Dudley Buxton's gag by introducing a double action release catch so as to be uppermost whichever side the gag is used. By the pressure of a button the ratchet is at once freed. It works extremely well and can be easily manipulated by either hand holding the gag. This specially designed stand which holds the little glass capsules of ethyl chloride is most convenient and should be appreciated by all who use this anæsthetic.

DIAGRAMS FOR TESTING BINOCULAR VISION AND FOR USE IN THE TREATMENT OF SQUINT.

WHEN an object is viewed with both eyes an image of it is produced on each retina. In consequence of the fusing of these images persons who possess binocular single vision see only one object and not two, but this faculty is not infrequently impaired owing to a want of harmony in the motility or refraction of the two eyes and a certain amount of binocular double vision is the result. A similar effect is produced if one eye is slightly displaced by pressure with the finger. Binocular single vision is an essential condition of stereoscopic vision or the perception of depth in solid bodies or curved surfaces, and its presence or absence may accordingly be tested by means of stereoscopic pictures. We have received from the publishing house of Wilhelm Engelmann, in Leipsic, a very convenient set of 20 pairs of diagrams selected for this purpose by Dr. W. Hausmann, together with a holder in which they may be placed at various distances apart indicated by a millimetre scale. The diagrams are of a simple kind, consisting only of circular and rectilinear figures and dots partly black on a white background and partly the converse of this. The two diagrams of each pair are on separate cards measuring about 2 inches by 3 inches. They can be viewed in any ordinary stereoscope, but for accurate work a special form of stereoscope can be obtained from Mr. Felix Tornier, Königsplatz 6, Leipsic. It allows ready movement of the cards in several directions and is provided with tinted glasses to equalise the images when there is a difference in the visual acuity of the two eyes. The price of the 20 pairs of cards is 2 marks and that of the special stereoscope is 11 marks.

THE REPORT OF THE COMMITTEE OF KING EDWARD'S HOSPITAL FUND APPOINTED TO SUGGEST MEANS FOR SECURING PROTECTION AGAINST FIRE IN HOSPITALS.

THIS report was briefly noticed in THE LANCET of Nov. 30th last but the subject is of such importance as to demand fuller consideration than was then given to it. The following is the text of the Appendices A and B.

A.

POINTS WHICH SHOULD BE BORNE IN MIND BY HOSPITAL COMMITTEES WHEN FRAMING REGULATIONS.

1. It is important to have some arrangement for summoning those who should be alarmed. In arranging the method for alarm it is necessary to avoid startling the patients unnecessarily. *Police whistles* distributed are worth consideration and would have the effect of summoning police aid as well. Every endeavour should be made, however, only to disturb the affected area.

2. Each building containing patients should have means of immediately dispatching information to the nearest fire brigade or police station and the nurses or others in charge should be instructed as to the proper mode of instantly sending for this external aid without waiting to see whether their own local appliances are sufficient or not. If the hospital is not on the telephone the staff should know where the nearest fire alarm post in the street is located and how to use it. This information should be given on *the* card of printed regulations. In order to save expense an offer might be made to the fire brigade authority to allow a public fire alarm to be placed at the hospital gate, which would be available for use by the public as well as by the hospital officials. If the hospital is on the telephone, the London fire

the greatest difficulty occurred in localising the abscess, which was then treated like an empyema.—Mr. R. Wood showed a female patient the subject of Myocarditis and Dropsy. Much improvement had followed the local application of tincture of strophanthus and belladonna over the heart.—Mr. H. Bell Tawse read a paper on Some Complications and Dangers of Nasal Surgery. He pointed out the mishaps which might occur in dealing with the middle turbinate and emphasised the importance of having free access to it by preliminary removal of deviations and spurs, advocating Killian's submucous resection as the best all-round method of dealing with them. Ethmoidal curetting for nasal polypi and ethmoidal suppuration was exhaustively discussed and cases were cited to illustrate such complications as necrosis of the frontal and superior maxillary bones, injury to the cribriform plate, and suppurative meningitis. He looked on the operation as unjustifiable in anyone over 60 years of age. He considered that in many cases of frontal sinus suppuration the dangers of radical operation outweighed the advantages, but hoped some means of preventing disasters like osteo-myelitis of the skull and meningitis would soon be found. Operations on the maxillary antrum were shown to be very free from complications and such post-operative sequelæ as dry rhinitis, ozæna, infection of healthy sinuses, middle-ear trouble, and the nervous breakdown which occasionally occurred during a tedious after-treatment were briefly reviewed.—The paper was discussed by Mr. W. M. Willis, Mr. J. Mackie, Mr. A. R. Tweedie, Dr. Hunter, and others, and Mr. Tawse replied.

ABERDEEN MEDICO-CHIRURGICAL SOCIETY.—A clinical meeting of this society was held on Jan. 9th, Dr. George Williamson, the President, being in the chair.—Dr. J. F. Christie showed cases of Lupus Erythematosus, Erythema of the Face, Luetic Skin Lesions of the Face, and Pemphigus Vulgaris.—Dr. A. W. Mackintosh, for Dr. G. M. Edmond, showed a case of Cerebral Tumour with a history of four and a half years. He also showed cases of Hodgkin's Disease and of Peripheral Neuritis.—Dr. A. R. Galloway showed three cases illustrating Cataract, a case of Moderate Myopia with fundus changes, and a case of Optic Atrophy. He also showed a well-marked case of Persistent Pupillary Membranes.—Dr. C. H. Usher exhibited drawings of a somewhat similar case.—Dr. P. Howie showed a case of Telangiectasis of the right axilla and upper arm. This patient had recently suffered from a suppurating gland in the right axilla which opened through the centre of the tumour without the occurrence of hæmorrhage.—Dr. G. Rose showed several cases of Congenital Dislocation of the Hip and of Club Foot. He also showed a case of Infantile Paralysis involving the quadriceps extensor cruris.—Dr. F. Kelly, for Mr. H. M. W. Gray, showed cases of Resection of the Elbow for tuberculous disease and injury, and two cases of extensive burns treated by preliminary scrubbing under an anæsthetic with subsequent dusting with equal parts of carbonate of bismuth and boric acid.

Reviews and Notices of Books.

Surgery, its Principles and Practice. By Various Authors. Edited by WILLIAM WILLIAMS KEEN, M.D., LL.D., Professor of the Principles of Surgery and of Clinical Surgery, Jefferson Medical College, Philadelphia. Vol. II. With 572 text illustrations and nine coloured plates. London and Philadelphia: W. B. Saunders Company. 1907. Pp. 920. Price 30s. net.

WE welcome the appearance of the second volume of this valuable system of surgery. The subjects dealt with in it include the bones, joints, muscles, and tendons; orthopædic surgery; and the surgery of the lymphatic system, the skin, and the nervous system. Dr. E. H. Nichols of Boston has contributed the chapter on Diseases of the Bones and he commences with a useful account of the structure of bone, for it is on the peculiarities of its structure that the special characteristics of the pathology of diseases of bone depend. We agree fully with the author that the correct interpretation of x ray photographs of bones is exceedingly difficult and this applies both to traumatic conditions and to those lesions resulting from disease. The author puts it well: "In cases in which the clinical diagnosis is difficult, the x ray examination is simply one of several means which must be employed, each of which must be given its relative value as a method of diagnosis. In some cases not only is diagnosis by the x ray difficult, but the x ray examination may be absolutely misleading. In other words, the x ray is an enormous advantage in the diagnosis of lesions of bones, but its value has been greatly over-estimated, and the possibility of its giving an entirely erroneous impression must not be overlooked, especially in medico-legal cases." This extract expresses very clearly the value and the dangers of the x rays as a diagnostic aid. The account of the diseases of bone is good but rather too brief.

Dr. D. N. Eisendrath of Chicago has written on Fractures. This is the most important article in the book and occupies more than 200 pages; it is clearly written and leaves little to be desired. The Surgery of the Joints has been divided between Dr. Nichols, who has written on the pathology, and Dr. R. W. Lovett, who has taken the rest of the subject—i.e., the clinical part. There is little need for comment but in the account of the signs of early tuberculosis of the hip-joint it should have been mentioned that one cause of the loss of the gluteal fold is the flexion of the joint which is always present. Even in a healthy hip a very little flexion of the hip-joint entirely obliterates the fold. Later, of course, the atrophy of the muscles makes more marked the flattening of the hip.

Dr. Eisendrath's article on Dislocations is almost as good as his article on fractures and the illustrations are excellent. The only criticism which we have to make is that there is no good reason why passive movement of a joint after reduction of a dislocation should be delayed for a fortnight. The sooner passive movement is commenced the better, for delay can only favour the formation of adhesions. After the fortnight's rest we are told that 15 minutes' passive movement twice a day is required. No such energetic treatment is needed if gentle passive movement has been started early, and though at first the movement is not free from pain the total amount of pain felt is much less than when passive movement is delayed for a fortnight.

Dr. J. F. Binnie's short article on the Surgery of Muscles, Tendons, and Bursæ contains all that is required. We are glad to see that he rejects entirely the "hernial" theory of a "ganglion." It is a collagenous degeneration in connexion with a tendon-sheath, occurring probably in a synovial fringe. Dr. Lovett has undertaken the section on Orthopædic Surgery. It is often difficult to say with exactness what should, and what should not, be included under this head. Here we find caries and other deformities of the spine, infantile paralysis, congenital dislocations, club-foot, and rachitic deformities. A very good account is given of Lorenz's method of treating congenital disease of the hip. Dr. F. H. Gerrish has contributed the chapter on the Surgery of the Lymphatic System. The most important portion of this section is that which deals with elephantiasis; it is well illustrated.

The fact that the chapter on the Surgery of the Skin and its Appendages is by Dr. John A. Fordyce is sufficient to guarantee that it is well written. In the account of rodent ulcer the value of radium certainly deserves mention, as in the hands of many the radium treatment has displaced most other forms of treatment for this condition. The value of ionic medication of many cutaneous abnormalities should at least have been referred to. The remainder of the volume is devoted to the Surgery of the Nervous System, Dr. W. G. Spiller writing on the pathology of the subject, Dr. George Woolsey on the surgery of the nerves, Dr. F. X. Dercum on traumatic neurasthenia, hysteria, and insanity following injuries, Dr. Da Costa on and mop are likely to prove of much greater value. Fire- and sand-pails ought certainly to be placed at points in readiness. Clothing and spare blankets should be distributed in various parts of the building for the patients' use in an emergency and not concentrated in one store to which access might be impossible. Asbestos blinds or curtains might be fixed ready to be drawn across staircase or corridor openings or on the several landings round the lifts; this would tend to localise a fire and check draught and smoke while the lift was in use for the removal of patients.

APPENDIX B.

Clause 1.—Frequent drill can alone prevent confusion in the event of an outbreak.

Clause 2.—A calm demeanour in the staff and the assurance that means are being adopted for their safety are most necessary to obviate panic amongst the patients.

Clause 3.—Especial care should be exercised that persons of a suitable temperament only are selected for this most important duty of conveying the patients to a place of safety. A cheap form of smoke-mask might well be kept in each of the patient's lockers. In addition to the superintendent and deputy of the staff brigade there should be a first and second in command of each ward who in the event of a fire in their particular ward should, under the general superintendent, take the command of the staff and direct the removal of their patients till their ward was cleared. These should be taught the best possible exit in varying circumstances in the event of their ward being threatened.

The report should be of value in leading those responsible for the safety of others under their charge to review the risks to which their particular buildings are subjected. The suggestion of the Commissioners in the body of the report that they should be consulted as to the site and details of any proposed new hospital deserves consideration, though this is practically done in London by the County Council. The insistence of the Commissioners as to absolute cleanliness should be, in the case of hospitals, unnecessary.

General remarks.—In the construction of buildings used as hospitals the following points are generally observed and cannot be too strongly insisted on:—1. The use as far as possible of incombustible materials. 2. The division of the building into more or less disconnected sections. 3. The avoidance of long corridors. 4. The provision of emergency exits. 5. The avoidance of all air spaces in floors, and round door and window frames, which last should be solid, not hollow as is necessary when sliding sashes are used. 6. The use of fire-resisting paints, care being taken that the woodwork is first thoroughly dry; such paint not to contain zinc chloride, as is sometimes the case, the fumes from which, given off when burning being insupportable by human beings. 7. The use of distemper and lime-white as a protection to woodwork. The avoidance of tarred felt and wood boarding beneath the slates. The use of small pipes and radiators now in vogue for the circulation of hot water minimises the risk of fire travelling along the channels hitherto necessary for the larger pipes. In any case in all troughs and channels, for pipes or wires, baffles should be placed to check the advance of fire by such means. We may refer our readers on these points to an article published in THE LANCET of Jan. 31st, 1903, p. 314, shortly after the Colney Hatch disaster.

In this connexion we are reminded that on Feb. 31st, 1903, at a meeting of the Metropolitan Asylums Board the working committee presented a report on the provision of water for protection against fire in the 29 hospitals, asylums, and institutions under its charge. Out of these 29 institutions eight, or over 27 per cent., were found to be more or less deficient. It would be interesting to know that these defects have since been remedied.

MEDICINE AND THE LAW.

Disposal of Infected Bodies.

A SOMEWHAT unusual application was recently made to the Birmingham magistrates by a solicitor on behalf of the Birmingham medical officer of health. He asked for an order to remove the body of a man from a private house to the mortuary. The body in question was that of a married man, 27 years of age, who died on Jan. 9th from consumption of the lungs, an infectious disease. The widow, who was left with three children, resided with another family of three at a back house in Bordesley, and therefore there were seven persons living in the same room where the body lay uncoffined. Evidence was given by the assistant medical officer of health of the city, who stated that it was necessary for the body to be removed. The widow, who gave her consent to the course which it was proposed to take, was trying to collect 30*s.* in order to pay for the burial. The magistrates made an order for the removal of the body to the mortuary. It is enacted by Section 142 of the Public Health Act, 1875, that where the body of one who has died from any infectious disease is retained in a room in which persons live or sleep, or any dead body which is in such a state as to endanger the health of the inmates of the same house or room is retained in any house or room, any justice may, on a certificate signed by a legally qualified medical practitioner, order the body to be removed at the cost of the local authority to any mortuary provided by such authority and direct the same to be buried within a time to be limited in such order; and unless the friends or relatives of the deceased undertake to bury the body within the time so limited and do bury the same it shall be the duty of the relieving officer to bury such body at the expense of the poor rate but any expense so incurred may be recovered by the relieving officer in a summary manner from any person legally liable to pay the expense of such burial. Any person obstructing the execution of an order made by a justice under this section is liable to a penalty of £5. When the local authority has provided a mortuary this section applies but where the Infectious Diseases (Prevention) Act, 1890, has been adopted the justice may order the body to be removed to any available mortuary. By Section 8 of the Infectious Diseases (Prevention) Act, 1890, it is provided that no person without the sanction in writing of the medical officer of health or of a registered medical practitioner shall retain unburied elsewhere than in a public mortuary or in a room not used at the time as a dwelling-place, sleeping-place, or workroom, for more than 48 hours, the body of any person who has died from any infectious disease. And by Section 10 of the same Act it is provided that where the body of any person who has died from any infectious disease remains unburied elsewhere than in a mortuary or in a room not used at the time as a dwelling-place, sleeping-place, or workroom for more than 48 hours after death without the sanction of the medical officer of health or a registered medical practitioner, or where the dead body of any person is retained in any house or building so as to endanger the health of the inmates of such house or building or of any adjoining or neighbouring house or building, any justice may on the application of the medical officer of health order the body to be removed at the cost of the local authority to any available mortuary, and direct the same to be buried within a time to be limited in the order; and any justice may, in the case of the body of any person who has died from any infectious disease, or in any case in which he shall consider immediate burial necessary, direct the body to be so buried. Unless the friends or relatives of the deceased undertake to bury and do bury the body within the time limited by such order, it shall be the duty of the relieving officer of the relief district from which the body has been removed to the mortuary, or in which the body shall be, if it has not been so removed, to bury such body and any expense so incurred may be charged by the relieving officer in his accounts and may be recovered by the board of guardians in a summary manner from any person legally liable to pay the expenses of such burial. The principles of the common law (i.e., apart from statute law) with respect to the rights of burial were laid down by Lord Chief Justice Denman, as follows:—

> Every person dying in this country and not within certain exclusions laid down by the ecclesiastical law has a right to Christian burial; and that implies the right to be carried from the place where his body lies to the parish cemetery. Further, to use the words of Lord Stowell, "that bodies should be carried in a state of naked exposure to the grave would be a real offence to the living, as well as an apparent indignity to the dead." We have no doubt, therefore, that the common law casts on some one the duty of carrying to the grave, decently covered, the dead body of any person dying in such a state of indigence as to leave no funds for that purpose. The feelings and interests of the living require this, and create the duty. ...... It should seem that the individual under whose roof a poor person dies is bound to carry the body decently covered to the place of burial; he cannot keep him unburied, nor do anything which prevents Christian burial; he cannot therefore cast him out, so as to expose the body to violation, or to offend the feelings or endanger the health of the living; and for the same reason he cannot carry him uncovered to the grave.—Reg. *v.* Stewart, 12 A. & E. 773.

upon them by the Act—namely, that after April 1st, 1910, no woman may habitually and for gain attend women in childbirth unless she is certified under the Act. In Part II. the provisions of the Act are very fully considered and in Part III. are given the rules framed under Section 3 of the Act for its proper administration, and approved by the Privy Council. The book concludes with a very interesting literary appendix. Dr. Atkinson is to be congratulated upon having written a most useful book containing a large amount of information on the subject of midwives and the Midwives Act not readily to be obtained elsewhere.

Hazell's Annual for 1908: A Cyclopædic Record of Men and Topics of the Day. Edited by WILLIAM PALMER. London: Hodder and Stoughton. 1908. Pp. 604. Price 3s. 6d. net.—*Hazell's Annual* has an established reputation amongst year-books and there is as much information as usual in the 600 pages of the present issue. The political section is carefully compiled and there are a great many facts of value to men engaged in a hundred kinds of commerce. A somewhat curious effect is produced by the fact that this book is absolutely alphabetically arranged; thus we find in juxtaposition the headings Costa Rica; County Councils Association; Crane, Walter; Cremation; Crete. Such medical information as the book contains is trustworthy and includes a brief review of the outstanding medical events of 1907, written with knowledge, and an obituary list of distinguished medical men. We venture to suggest that the Royal Society of Medicine might find a place in a list of "Scientific Societies and Institutions" which claims to give particulars of "the more important and active" of these bodies, even though the list "does not pretend to be exhaustive." The Royal Society of Medicine is most certainly both as important and active as, let us say, the Palæontographical or Ethnological Societies.

A Treatise on Surgery. By GEORGE RYERSON FOWLER, M.D., Examiner in Surgery, Board of Medical Examiners of the Regents of the University of the State of New York; Emeritus Professor of Surgery in the New York Policlinic; Surgeon to the Methodist Episcopal Hospital; Surgeon in Chief to the Brooklyn Hospital; Surgeon to the German Hospital. Containing 888 text illustrations and four coloured plates, all original. London and Philadelphia: W. B. Saunders Company. 1906. Vol. I., pp. 722. Vol. II., pp. 714. Price £3 3s. net.—It requires no small degree of courage for a surgeon nowadays to undertake the writing of a treatise on surgery. Even text-books for students are now large, but a complete treatise on the science and art of surgery is indeed an enormous undertaking. The amount of time which these volumes must have taken must have been very great, for the work is fully ahead of the present day, and the references which the author gives show that he is conversant with the chief current literature. The most striking point about the work is the wealth of illustration and we meet with none of the old illustrations which have done duty so often before. Here they are all original and they have evidently been chosen with great care. A few points call for criticism. It is stated concerning retropharyngeal abscess that "with the exception of the rather rare form of the latter resulting from phlegmonous inflammation of the submucous tissue or suppurating lymphadenitis of a retropharyngeal lymphatic gland, retropharyngeal abscess arises almost exclusively from Pott's disease in the cervical region." This statement does not give a correct idea of the relative frequency of the causes of abscess behind the pharynx; in this country at least the cases not due to caries form a large proportion of the whole. No hint even is given that the abscess can be drained very satisfactorily through an incision behind the sterno-mastoid. In the description of the operation of wiring a fractured patella the author says, "irrigation must not be employed." Whether irrigation should be used or not depends on the solution employed; a strong irritating antiseptic would be harmful but hot normal saline solution could do no harm. In the description of Pirogoff's amputation the section of the os calcis is described as being made through the plantar incision, and then it is said "or from behind forwards and downwards, according to Günther's modification"; this description can only apply when the os calcis is sawn from above after the ankle-joint has been opened. But these are only small matters and we approve highly of the work as very suitable for anyone in general practice who wishes to keep abreast with the present position in surgery.

On Osseous Formations in and about Muscles due to Injury. By ROBERT JONES, F.R.C.S. Edin., and DAVID MORGAN, M.B.—This monograph consists of a reprint of a series of articles which appeared in the *Archives of the Roentgen Ray* during 1905 and 1906. Gathered together in this form we have a very valuable treatise on this subject, embodying as it does a synopsis of all the cases which have been recorded of this condition by observers at home and abroad. The present state of the pathology, diagnosis, and treatment of the disease is very fully related and not the least attractive part is the series of some two dozen radiographs taken from the more interesting of the cases which came under the observation of the authors themselves. These have been reproduced in a manner which is worthy of much praise. We are not aware if the monograph is obtainable in the ordinary way but we can commend it to the careful study of those who are fortunate enough to receive a copy.

A Primer of Psychology and Mental Disease. By C. B. BURR, M.D. Third edition. Philadelphia: F. A. Davis Company. 1906. Pp. 183. Price $1.25 net.—This manual has already passed through two editions and in the preface of the present volume the author states that he has re-written the parts dealing with the various insanities to bring them into line with the more modern classification of mental disorders. The book seems to have been written primarily for "use in training schools for attendants and nurses," but Dr. Burr has also endeavoured to adapt it for the medical student and practitioner. It is most difficult to embrace the requirements of both the lay and the professional reader, for either the book must be too technical for the former or too elementary for the latter, and this is rather the case in the present manual. The opening remarks of the psychological portion presuppose some knowledge of the subject, otherwise they would be almost unintelligible, for the descriptions are very condensed. Certain important subjects seem to be omitted—for example, we can find no special remarks about attention. The second part of the book is devoted to a brief description of insanity. The author largely follows Kraepelin's classification and some of his accounts of the various mental disorders are lucid. In others the subject-matter is so condensed that the student will have difficulty in grasping the important points. For example, in paranoia the author does not point out that the characteristic mental attitude of the patient is that the delusions become progressively more systematised throughout the illness; it may be implied in the description but it is not definitely stated. The chapters devoted to the medical and nursing management of cases are good and they will be found very helpful to the beginner. In fact, this remark applies generally to this manual, for it may be said fairly to fulfil its object which is that of an elementary account of "mind, normal and diseased."

La Pratique de la Médecine. Par W. OSLER, Professeur Royal à l'Université d'Oxford. Traduction Française sur la 6^e édition, par les Docteurs M. SALOMON, chef de Clinique à la Faculté, et LOUIS LAZARD, ancien interne de l'Hôpital de Rothschild. Préface du Dr. PIERRE MARIE. Paris: G. Steinheil. 1908. Pp. 1224. Prix Fr.25.—This interesting

see the liquid in the bottle. Here is the liquid; here is the vaporiser, and the vapour is discharged into the nose, and with a little practice it can be inhaled into the lungs. As my lord said, there is nothing special about the design of the spray and, so far as the apparatus concerned as a vaporiser, the only thing there is special about it is the care with which it is constructed, so that it shall produce vapour and not spray, vapour being the thing which is required for this purpose. No doubt the most valuable part of the remedy is this liquid, which was the discovery of the plaintiff's brother.

Mr. Justice RIDLEY: You say it is vapour and not spray?

Mr. DUKE: Vapour and not spray; it produces a vapour. The plaintiff understands the mode of operating it, and I daresay in the course of his evidence he may be able to show the distinction of it, but practically this produces a dry product; it produces a vapour, the dampness of which you do not discover. Of course, it must be damp because the particles of the liquid are dispersed very finely, but if you discharge it against blotting-paper I think you will find that instead of damping the blotting-paper so that you see the wetness upon it it will leave the blotting-paper with an appearance which you could barely distinguish, if you could at all, from its previous appearance. It scatters the particles of the fluid into a very fine state of distribution. As I was saying, I have no doubt apart from the care in the mechanical production of the vaporiser which is necessary for the efficient action of that apparatus, the most valuable part of Dr. Tucker's remedy is the liquid, the constituents of which he discovered and the constituents of which the defendants seek to discuss here. They profess to have discovered what the constituents are. I am not concerned to know whether they have or not, but they profess to discuss them here; and I suppose if the plaintiff had a valuable discovery and had an effective remedy, so far as any special knowledge the plaintiff had, if they are able to establish their proposition, if they do not destroy the plaintiff's character, at any rate destroy to some extent, or impair the value to him of the remedy which he is selling under circumstances which I will tell you, that is not a very material matter. That is the treatment, as it is called, which the plaintiff deals in. The plaintiff, for several years after his brother had made what he regarded as his discovery in the composition of the liquid which is used in the treatment, was engaged, under his brother's supervision, in the business part of the transaction of dealing with the remedy in the United States. In the year 1899 he came to England with a power of attorney from his brother—his brother had had an agent in this country—and either practically established or took over the business of selling this specific in this country, and since the year 1899 the plaintiff has made it his business to sell this specific in this country. His mode of dealing with the specific and the mode of carrying on business is what is first of all assailed in the libel which the defendent has published. His dealings are alleged by the defendant to be fraudulent—at least, the defendant does not condescend to any detail of any charge of fraud, but he says the plaintiff's dealings are such that it is fair comment upon him to say that his dealings are fraudulent. I do not quite understand myself how it can be a fair comment upon a man to say that his dealings are fraudulent unless they are fraudulent, and it may be that in the course of this case some submission may have to be made to my lord, and my lord's ruling obtained as to whether it is possible for a defendant who has alleged fraud and fraudulent dealing against another man to come into court and say, "Well, whether your dealings are fraudulent or not it is a fair comment upon you to say that they are fraudulent dealings." This is the position among others which the defendant in this action has taken up. I shall have a word or two more to say to you about that later, but it is an astounding position, and fatal, of course, to the reputations of all men who happen to be assailed if it is enough to come into court and say, "Well, I consider your dealings are fraudulent, whether they are fraudulent or not."

The plaintiff came to this country with his brother's power of attorney in 1899. Since that time he has had, and has used, the exclusive right of supplying his brother's remedy. Gentlemen, when I come to read the libel to you in this case you will see that the defendant in this case when he published his libel did not know anything about the plaintiff. Let me tell you this, which I shall follow up presently: The plaintiff has never advertised this remedy in the newspapers.

It is a common thing that specific remedies, whether they are valuable or whether they are spurious (there are valuable remedies and there are spurious remedies) are advertised in newspapers, and mere rubbish is passed off which is quite useless in some cases—at least, so it is said, and probably quite truly said, and the public are defrauded by that means. The plaintiff has not advertised, and does not advertise, in the newspapers. He has a pamphlet written, I think, by Dr. Tucker; and he has some terms of dealing which I shall show you presently, and he has instructions for the use of the inhaler. The use of the inhaler is simple enough if you understand it, but if either of you tries for the first time to inhale into your lungs a vapour through your nose you will find you need a little practice to do it; it is not quite so simple as it might be. There is a natural indisposition of the internal organs to receive anything from the outside; at any rate, it is not simple without instructions. The plaintiff has this pamphlet which is here, about which presently he will go into the box and be cross-examined. He has the terms of business which are here and he has instructions for the use of the specific, and he has a considerable number of agents whom he appoints for the purpose of selling his remedy, and, as far as one can see, those are the methods of honest business. Besides the pamphlet to which I refer and the other papers and the services of the agents, he has the recommendation of persons who have become informed of the usefulness of the specific and who largely recommend it, and by those means, without advertisement in the newspapers, without any other resort to the means of publicity than those I have mentioned to you, the plaintiff since the year 1899 has built up, as he will tell you, a large lucrative business. There is one other thing which I ought to tell you which lies at the bottom of the plaintiff's methods of business. When an applicant desires to try this specific he receives it for a fortnight on trial gratis. I know this speech will sound to you, or may sound to you—it will not justly when you know the facts—as something of the nature of a puff or panegyric on the plaintiff's business. Gentlemen, the plaintiff has not sought to come here and I am bound to tell you everything that will show that this attack on the plaintiff is groundless. The plaintiff, upon an application for this specific, supplies it for a fortnight on trial and all that happens with regard to it is contained in the terms of business which are here. Perhaps I might hand them up, because I shall have to refer to them. At the end of the pamphlet, after Dr. Tucker's account of the remedy and recommendation of it, there is a memorandum. Perhaps I had better read the whole of it, because I do not know quite where it is suggested the fraud on the part of the plaintiff lurks in these business dealings: "Memorandum. 1, Time of trial, two weeks in United Kingdom only. 2, Price of treatment, consisting of Atomizer, wood case, and four ounces of fluid, £3." I have something to say to you about that presently; it is said to be a high price. It would be a high price if the specific were rubbish, but if the specific is, as I think I shall show you by overwhelming and unquestionable evidence, a specific which defeats the oncoming attacks of asthma, the specific is, of course, of very great value, and the discoverer of it, and those who exercise his rights, are entitled to the reward of having possession of them. "3, To be paid for at end of two weeks, if satisfactory. 4, If not satisfactory at the expiration of the trial, the outfit, with what fluid there may be left, to be returned by Parcel Post. 5, One half-ounce of fluid will be sent with the Atomizer for trial, which is not included in the four ounces. 6, No more fluid will be sent for trial; you will be careful and not spill it. Keep a cork in nozzle of Atomizer when not in use. 7, If you do not wish to continue the treatment after two weeks' trial, return the Atomizer, with what fluid there may be left; if you desire to continue the treatment, remit £3. 8, As soon as the treatment is paid for I will send you two ounces of fluid by post, and the other two ounces on application when needed. The fluid precipitates a sediment by long standing, which is liable to choke the liquid tube, which will explain why only two ounces are sent at one time. 9, After the four ounces of fluid is exhausted it will cost you eight shillings per ounce, which lasts from two to four months. 10, Extra bulbs for the Atomizer, 2*s.* each. 11, Extra liquid tubes, 2*s.* each. Atomizer to be sent in to have the tube adjusted properly. 12, Cash must accompany all orders for fluid, bulbs, and tubes. 13, When sending telegrams, give initials and sufficient address. 14, Postage to foreign countries to be paid by patient. (Signed) A. Q. Tucker.

Effusion. Two cases of Empyema in which recovery took place after simple aspiration are recorded by Mr. Herbert W. Chambers.

University College, London, Union Magazine.—The December issue of this magazine does not contain any directly medical material. There are, however, several references to the adventures of medical members of the College in connexion with the celebrations of the Brown Dog's effigy, a theme which seems to have moved the writers to outbursts of rhyme, no doubt on the principle that "si natura negat, facit indignatio versus."

St. Thomas's Hospital Gazette.—A Presidential Address, delivered by Dr. J. J. Perkins before the Medical and Physical Society of the Hospital forms the main substance of the December issue of this journal. Dr. Perkins reviews the history of our knowledge of tuberculosis as an infective disease and points out that evidence is accumulating in favour of the origin of many cases in an intestinal infection by bacilli of bovine origin. An abstract of some remarks made by Dr. J. B. Leathes in opening a discussion on Diabetes gives an interesting summary of some recent work by Pflüger on this subject, the tendency of which is to discard the theory of a pancreatic secretion as at fault in this condition, and to revive the view propounded of old by Thiroloix and others that the disturbance following pancreatectomy is really due to interference with nerves which control the glycogenic function of the liver.

Guy's Hospital Gazette.—A clinical lecture by Dr. W. Hale White published in the December number of this magazine deals with the diagnosis of an abdominal swelling which presented the characters usually associated with a pancreatic cyst. Dr. Hale White points out that this is a rare condition, only one case of a single cyst having occurred in 6708 necropsies (there were also one case of hydatid of the pancreas and two of smaller multiple cysts). The tumour in this instance proved to be a sarcoma growing from the back of the abdomen but its point of origin was not exactly determined. In the January issue is published a clinical lecture by Mr. A. W. Ormond on Injuries to the Eye, in which he records two cases successfully treated by the Haab magnet.

London Hospital Gazette.—The medical matters dealt with in the December number of this magazine are rather fragmentary in form. The first article is part of a clinical lecture by Mr. J. Hutchinson, jun., on Umbilical Hernia and a later contribution is a continuation of Dr. F. J. Smith's review of the medical aspects of the recent Workmen's Compensation Act. The clinical supplement contains an abstract of some remarks by Dr. J. Biernacki on Diagnosis of Common Fevers but except in the case of diphtheria the summary is so brief as to afford little help.

St. Mary's Hospital Gazette.—A paper read before the Hospital Medical Society by Dr. Reginald H. Miller deals learnedly with acute poliomyelitis and some allied conditions, notably polio-encephalitis, which is suggested as a cause of some cases of rapidly fatal illness occurring in institutions. The use of such terms as "polio-encephalomyelitis" and "the cerebello-rubro-spinal system" suggests that the neurologists are running the dermatologists close in the matter of polysyllabic nomenclature.

The Broad Way, or Westminster Hospital Gazette.—The editorial notes in the December issue of this gazette are chiefly devoted to the "Brown dog" disturbances. Serious medical matter is only represented by a continuation of Lieutenant C. G. Browne's paper on the treatment of syphilis in the army, the value of iodipin being here noted, as well as that of the Zittman treatment in obstinate cases, while the suggestion is made that intramuscular injection might be more often employed in out-patient practice.

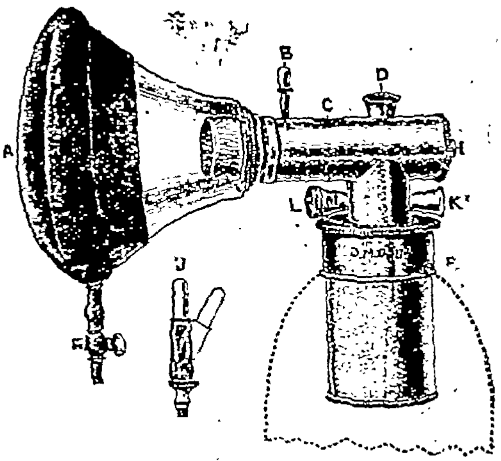
St. George's Hospital Gazette.—With the December number is included a good portrait of Sir T. Clifford Allbutt who is an old St. George's man. An interesting account is given by Dr. H. D. Rolleston of the methods of medical education prevalent in America; apparently a smaller amount of systematic lectures is inflicted on students there than here, but more laboratory work is required. The system of examination is also different and Dr. Rolleston seems to think that on the whole it is better than ours.

New Inventions.

THE IMPROVED "IDEAL" INHALER FOR ETHYL CHLORIDE AND OTHER ANÆSTHETICS.

THE features of Mr. Vernon Knowles's inhaler (made by the Dental Manufacturing Company, Lexington-street, London, W.) are: 1. Its adaptability for the use of ethyl chloride alone, with nitrous oxide, ether, chloroform, or mixtures of chloroform and ether. 2. As it gives complete control of the amount of anæsthetic given it increases the safety of the patient. In the case of chloroform it does not supply a measured quantity of vapour but allows the anæsthetist to use the drop method which with skill gives a fairly accurate dosage. 3. The extremely wide bore supplied prevents any distress in breathing. 4. The apparatus is so constructed that its component parts can be rapidly dissociated and sterilised. The apparatus consists of a celluloid face-piece fitted with studs. Two air pads of small and large sizes are supplied which are attachable to the studs and thus do not get out of position when once adjusted. One face-piece can be made in this manner to suffice for children and adults. The face-piece fits on to the apparatus and has a collar with two milled rings which prevent its rotation. The horizontal arm, that which carries the face-piece, is provided with two valves, one for air and the other for the anæsthetic; as the former is closed the latter is opened, and these enable the anæsthetist to give the anæsthetic slowly and gradually. The handle or lever which controls these valves unscrews and allows the inner barrel to be withdrawn for cleansing. Two inner barrels are supplied, one for use when nitrous oxide is employed, the second for all other anæsthetics. These barrels when out of use are kept in closed metal cases which prevent them becoming soiled. The outer valve C (Figs. 1 and 2) is placed between the lever B which works the valves and D the feed-funnel which communicates with the sponge-holder G. It will be seen in Fig. 2 that a space (H H) surrounds the sponge-holder and this insures free respiration even when the sponge is in position. As the patient's exhalations pass around the sponge there is less liability to its freezing than was the case when all the air had to pass through the sponge saturated with ethyl chloride or other anæsthetic. The feed-funnel D is used when the

FIG. 1.



dried up or sediment may deposit, as has been pointed out; but a few drops of it produce the vapour which is required, as I understand, and so it is not a thing which is rapidly used. In the year 1906, as it is said, Cushing died and he died somewhat suddenly. His death is said by the defendants, and I daresay truly, to have been the subject of an inquest before one of the London coroners. The defendants have produced newspaper extracts and things of that kind which make it pretty clear that Cushing's death was the subject of an inquest before one of the London coroners. What took place there I have no means of knowing except at second hand. It may be that the defendant will tell you whether anything occurred there which would have justified inquiry with regard to Mr. Tucker or with regard to this specific. Nothing could have taken place there which would justify an attack upon Mr. Tucker, because Mr. Tucker obviously could not be a party on an inquiry as to a death, which is what is the nature of an inquest, and he was not a witness and had no sort of notice or knowledge either of the death of Mr. Cushing or of any inquest upon him; but the defendants say that the inquest took place and I will tell you presently what further they say about it. All I ask you to bear in mind is that Mr. Tucker had nothing to do with the inquest and was not present there, so that whatever took place there, the proceedings being *ex parte* as far as Mr. *Tucker is concerned, could only have* been ground for some inquiry with regard to Mr. Tucker or with regard to his specific. In that state of facts it was that some time afterwards, I think two or three months afterwards, the defendant published in his newspaper the libel which is complained of in this action. I will read it to you.

Mr. ELDON BANKES: Would you mind reading it from THE LANCET?

Mr. DUKE: I do not mind using THE LANCET.

Mr. ELDON BANKES: I will hand you some copies of it.

Mr. Justice RIDLEY: Have I got it?

Mr. DUKE: Your lordship has it in the pleadings.

Mr. Justice RIDLEY: I should like to see it in THE LANCET. (Same handed to his lordship.)

Mr. DUKE: If your lordship will refer to page 701 you will see it before you at the bottom of the left-hand column.

Mr. Justice RIDLEY: Is it correctly set out in the pleadings?

Mr. DUKE: Yes, I think so.

Mr. Justice RIDLEY: It is much easier to read in the statement of claim.

Mr. DUKE: Yes; but my learned friend wants it from the paper and if I can oblige my friend I will. Gentlemen, in the course of this case, which is not likely to end before lunch, I expect you will have opportunities of reading this again, but I will read it to you. It is under the heading of "Notes, Short Comments, and Answers to Correspondents," where attention concentrates for the incidents which can be effectively put in a small space.

QUACK ADVERTISEMENTS.

> In the course of an *inquest held at the beginning of the year it was* stated that a labourer who had died from consumption had been using *Dr. Tucker's Asthma Specific Inhaler, for which* he had given, according to a newspaper report which has reached us, 3 guineas, while the material with which he sprayed himself cost him 8s. an ounce.—[Note the words "sprayed himself."]—Dr. F. J. Waldo, the coroner, rightly stigmatised this kind of dealing as a fraud, and it is a humiliating thing for journalists to remember that such frauds could not be committed with any profit to the quack save with the coöperation of the press. A correspondent has recently sent us a collection of advertisements of so-called proprietary medicines which he had cut from papers of reputation in the country, inviting our opinion of them. Our opinion is that the misery wrought by quacks must be unknown to a good many proprietors of newspapers, or they *would hardly* share with the quacks the plunder extracted from the public, mainly from the sick poor. *The remedy is in the* hands of the public, who have only to signify their displeasure, at reading in their journals invitations to be *robbed* and *poisoned*, to find those invitations immediately cease. But the public are largely uninstructed and credulous, and, alas, those *responsible* for the conduct of many of our journals take no trouble to enlighten them. They prefer to regard all protests against quack advertisements as emanating from the narrowness of the medical profession. This is certainly a convenient faith, but how it can be truly held by educated people passes our comprehension.

That is the libel. It is open to everybody who pleases to discuss quack remedies, to discuss specifics, to say in proper and moderate language that it is not in the public interests that any kind of specific for the treatment of any ailment should be sold by anybody who is not a registered medical practitioner; it is quite open to any man who likes to discuss those facts in any moderate and proper terms and with any strength of criticism; but I submit to you, and I believe you will hear it is the law of this country, that you may not accuse a man of fraud, of fraudulent dealing, of being one of a class of people who poison and rob the credulous poor, without having substantial warranty for the charges you make; and of substantial warranty for the charges which are contained in this very gross libel upon the plaintiff when you come to examine what the defendants have set up in their defence in this action I think you will find there is not a shadow. Just let us see for the moment before I part from this what it is said. It is said, as you will observe, that this kind of dealing—that is, the plaintiff's kind of dealing—is to be rightly stigmatised as a fraud; and it is said that the people with whom the plaintiff is classed are people who plunder, who rob and poison the credulous poor; and that all that is published by way of statement and observation with respect to the specific which I have been describing to you, with respect to the business which I have been describing to you, carried on in the manner which I have mentioned to you, and with regard to the plaintiff who will shortly go into the box before you. I told you that it was pretty apparent that the editor of THE LANCET, or the person who wrote this on behalf of the defendant, knew nothing about Mr. Tucker and his specific. Let us see whether he knew anything. Do you notice that what he says is that it was correct to say that the man whose body had been the subject of the inquest had bought a liquid with which he "sprayed himself." If he knew anything about this remedy he must have known perfectly well that the man did not spray himself, that it was quite untrue and a gross misrepresentation of the fact, and that this was a treatment which produced a vapour, and not very palpable vapour. He must have known that. Then do you notice that he describes Mr. Tucker as one of a class of quacks advertising in the public newspapers who are the public nuisance and danger he mentions there. I must do the proprietor and editor of THE LANCET the justice to suppose that they did not gratuitously make a false charge against the plaintiff of being a quack who advertised in the newspapers and by means of newspaper advertisements. You see he says "plunder the public"; so that when you look into this before you hear anything from the defendant it is pretty clear that he did not know anything about Mr. Tucker or his remedy. My clients were quite willing to suppose that that was so. Mr. Tucker did not at once become aware of what had been published in THE LANCET. If need be he will tell you how he ultimately became aware of it; it was brought to his notice. Then his solicitors, Messrs. Venn and Co., of whom Mr. Venn is the representative, wrote a perfectly proper letter to the editor of the defendant's paper—a long letter. I am going to read it to you because it was written by a man, Mr. Venn, whom I will call before you, who was in a position to say that his life, which had been practically impossible as a professional man because of constant attacks of asthma, had been restored to him as the comfortable life of an ordinary person by the use of this specific, and who naturally wrote with some detail and with some little warmth about this matter. But he wrote a letter which enabled the *defendant*, if the defendant did not desire wrongfully and oppressively to crush the plaintiff, and *wrongfully* and *oppressively* to hold him up to odium, to retrace his steps. This is the letter of *the 9th of May, 1907, to the Editor of THE LANCET*: "Sir,—Mr. A Q. Tucker, of 'Onaway,' Half Moon-lane, Herne Hill, has consulted us *respecting* a *paragraph* headed 'Quack Advertisements' appearing in your issue of the 9th March last, which has very recently come to his notice. Our client is the general manager in England for Dr. Tucker and has a considerable personal and direct interest in the sale and distribution of the atomizer and specific. The statement with reference to the inquest and to the sale of the inhaler (or atomizer) and the spraying material (or specific) that 'Dr. J. F. Waldo, the Coroner, rightly stigmatised this kind of dealing as a fraud,' and the use of the word 'quack' in connexion with Dr. Tucker"—he is the plaintiff's brother—"are the subject of very serious complaint by our client. *No* opportunity of being present at the inquest was given to our client. Had he been present he *would have been* able to satisfy the Coroner that the charge of fraud, if in fact such a charge was made, was absolutely without foundation. Our client has not seen any report of the inquest which supports your statement that the Coroner attributed fraud or blame to brigade should be called by telephone *and* by fire alarm post in the street. The following slip should be posted near the telephone, if any:—

"IN CASE OF FIRE."

Ring up in the usual way.
Say "Put me on the fire brigade."
When answered: say—
"Fire at   Hospital,   street," &c.—*and* any detail that your presence of mind dictates, viz.: Large—small—roof—basement—&c.

3. The regulations of the hospital should provide organisation that will immediately stay "panic" and guide the patients to safety. If alternative staircases are not available, anything like a "cul de sac" where several are accommodated, particularly on upper floors, requires special attention and consideration.

4. Every hospital should have within its walls some "first aid" apparatus to deal with the outbreak. As the probable position of any outbreak can generally be foretold, the risks should be located and studied beforehand. Roof, kitchen, storerooms, cupboards, heating places, workshops, laundry, &c., are examples of likely danger points. Fireplaces and guards, gas fittings (especially swinging gas fittings), curtains, rubbish collections, and places where candles and matches are used near clothing and bedding, should also be studied. Fire drills adapted to the special danger of the particular hospital should be quietly arranged periodically. This location of risks is the essence of effective fire drill. Certain of the staff should be detailed to handle the hospital fire appliances, and they should *know* this is their job. They should be so selected that some will always be present. The whole number should periodically be summoned to the different "fire risks" for drill. An ordinary mop and bucket will prove useful in the early stages to splash water and anyone can use them. Should the fire be due to electricity or upset of oil, be careful in applying water, but rather endeavour to smother with sand or wet blanket till the brigade arrives.

5. Printed instructions should be posted up freely, so that all are reminded that fire is a possible contingency. These instructions should deal with all the foregoing points, with any additions or amplifications appropriate to the particular hospital or to its appliances.

B.

POINTS WHICH SHOULD BE REMEMBERED BY THE STAFF WHEN AN ALARM TAKES PLACE.

1. On the discovery of a fire or on smelling smoke the staff and employees should not run about aimlessly or shout or shriek, &c., but quietly think and act on the instructions for raising the alarm.

2. The first object is to prevent "panic" among the patients and visitors, if any.

3. If the fire brigade has been called the actual fire damage should not be much in the thoughts of the staff. It is imperative to see to the removal of patients who are in danger to safety, which is, as a rule, out of the smoke area, and preferably outside the building involved if a comparatively small one, or into a separate block if a large one. In a densely smoky atmosphere a wet flannel over the face is beneficial.

4. Those detailed for appliances should go to their duty at once and endeavour to check the progress of the fire. It would be as well also for someone in authority on the spot to detail those who are to remove patients and also those who are to receive them and see to their proper clothing and comfort.

N.B.—As far as the details of the actual steps to be taken when an alarm takes place are concerned the printed regulations drawn up by the individual hospital and the periodic fire drills should ensure that *every member* of the staff knows what is his or her duty in the event of an alarm of fire.

While all will be able to appreciate the points emphasised by such authorities as the Commissioners—both formerly chiefs of the London Fire Brigade—we have ventured to add a few comments arising from a perusal of the suggestions made therein.

APPENDIX A.

Clause 1.—Police whistles may not be without merit, though to many they are indistinguishable from cab-calls. Automatic thermometric alarms might be useful if fixed in store rooms, workshops, and places removed from the constant presence of the attendants, such alarms to ring, say, in the porters' lodge or engine room where someone is always on duty. From this point there should be telephonic communication with the rest of the building and with the nearest fire stations. There are several of these automatic fire alarms in use throughout the country, those operated by the expansion of a metal slip possibly being preferred. As an example the following is a description of one of the best known alarms—viz., "The Pearson Automatic Fire Alarm." At certain points where the risk is considered greatest or where there is the least chance of detection a small instrument is fixed called a thermostat, with this contact is made and an electrical circuit is formed by the expansion of a small metal strip capable of being so finely adjusted that a connexion can be made at any desired temperature. These are wired in parallel on looped circuits connected to an indicator. Should any undue heat occur where the thermostat is fixed a bell rings and the position of the one affected is shown on the indicator. At the point at which the indicator is fixed, say the porters' lodge, one of three courses may be adopted: 1. A private telephone can be installed by the General Post Office for an annual charge of, say, 40*s.* to 60*s.* direct to an indicator at the nearest district fire station. 2. A wire may connect to the central office of the fire alarm company, where a duplicate indicator receives the alarm consecutively with the indicator at the hospital. The operator then telephones by a private wire to the nearest fire station. 3. Communication may be made to the fire station by the regular telephone service as explained in the committee's report.

Direct communication with the fire station is preferable for a hospital where there is someone always on duty near the telephone and indicator, as all delays or misunderstandings incident to the telephone are avoided. This direct system is adopted by several London hospitals independently of the automatic alarm. Instantly on pressing a button or lifting the telephone receiver a shutter falls on the indicator at the fire station giving the name of the hospital, while a bell rings till the call is answered. Should the call be at night the fireman on duty presses a lever which rings a bell in each of the men's rooms, and at the same time switches on all lights. At once an engine and an escape are turned out. While this is being done he calls up the central fire station of the district and by telephone gives notice of the fire. The central fire station then gives notice to the other district stations in its circuit, thus: On the ceiling of each district station are fixed a red and a green electric lamp; by pressing one or two buttons at the central station all bells are set ringing at the district stations called and either one or both of these lights are switched on, red for an engine or green for an escape. The men hurrying down at once see what is required and all help to despatch the team wanted. Meanwhile, instructions as to the locality of the fire are received by telephone. Thus within a minute of the call five or six engines with escapes can be sent to a fire without denuding any one station of its resources. Each central office is in direct communication with the headquarters in Southwark, which can instruct other central stations should it be necessary to send more help from their district branches.

Again, electric bells might be fixed from various points, say from the nurses' duty rooms, to ring in connexion with fire indicators at some such point as above mentioned. Such bells should be tested daily and batteries examined.

Clause 2.—These suggestions are distinctly good. Flare-lights, such as are in use in the navy for lighting buoys at sea when thrown to a man overboard, might be fixed at several prominent external points and fired by triggers in the building. These flares might be partially inclosed in metal boxes, perforated with the word "Fire." Or, again, steam or pneumatic whistles might be fixed externally to each ward or section. Direct communication with the nearest district fire station by a special wire and bell is the best and surest way. We understand that in America for a moderate annual fee any large building can be placed in direct communication with the nearest district station. In the station is a large dial round which are the names of the institutions connected with the station. A bell rings and a pointer moves round the dial and stops at the name whence the call came, which is answered back.

Clause 3.—Everything depends upon organisation if panic is to be avoided. Those in authority should confer with some responsible fireman whose opinion is of value as to possible risks and the best methods of organising the staff. The staff should be trained and drilled at their work, not forgetting the practice of the removal of members acting as patients properly clad. Many students and others associated with hospitals might gain valuable experience in this work by joining one of the many suburban fire brigades, if only for a short time. Alternative staircases are now mostly provided in new buildings owing to the action of county councils and local authorities. Those patients whose powers of locomotion are most defective should have preference of others as to the most favourable position for exit in the event of an outbreak.

Clause 4.—A point requiring very serious consideration is a difficulty with regard to training a fire staff owing to the heavy charges made by some water authorities for breaking the seal of a fire hydrant, thereby tending to prevent efficiency in the staff and the testing of the hose and valve. In some cases the annual charge for these mains is such as to prevent the connecting up of fire appliances provided in new buildings. If hand grenades or tubes containing chemicals are relied on practice is necessary in the use of them. There is a knack in directing their contents to the right spot which is not to be acquired on the first attempt during moments of excitement. The suggested pail of water specific, together with a suitable spraying instrument, could be obtained from any chemist at a cost of *8s.* to *9s.* (*c*) Advertisements of so-called proprietary medicines." That was the defence which they put in at that time. Let us understand what was the meaning of it. What they had said was: Your, Mr. Tucker's, system of dealing in this specific is a system of fraudulent dealing. The only defence, as I understand the law—but I am speaking with unfeigned respect to what you will hear from the Bench in the matter—the only defence which a man can effectually make when he has accused another man of a system of fraudulent dealing is to say: you were guilty of a system of fraudulent dealing. That defence the defendant has not dared to make, did not dare to make then, and has not dared to make now; but he has played round it to suggest the defence which he dare not honestly raise.

Mr. Justice RIDLEY: He says that the fraud suggested by the coroner is the fraud arising out of *the fact that there is* a Government stamp on the inhaler.

Mr. DUKE: So he says.

Mr. Justice RIDLEY: That is right, is it not, Mr. Bankes?

Mr. ELDON BANKES: No, my lord, not quite.

Mr. DUKE: I do not quite know. It is ingenious and it may be a little subtle, but we shall get to the bottom of it.

Mr. Justice RIDLEY: *That is the first part of* it, but there may be something more in it. I think there is another element in it under the head (*b*).

Mr. DUKE: Yes; I was going to take them seriatim and see what he does say. I was suggesting at the moment that it is not enough unless there is an allegation that there is a fraud.

Mr. Justice RIDLEY: Then that fraud is quite a different fraud from that which is suggested in the article.

Mr. DUKE: Absolutely, *and it is not the plaintiff's fraud.*

Mr. Justice RIDLEY: That will be for the jury. It is quite true. I must not say that.

Mr. DUKE: I have to point out what is the nature of the issues which are raised here, and how it is attempted to get rid of the consequence of an open and deliberate charge of fraud upon the plaintiff in his system of *dealing in this specific.* A charge of a fraudulent system of dealing, a charge of plundering the public by means of dishonest advertisements, and of poisoning the public—poisoning the credulous, ignorant people. That is the charge. Now I am going to see what he says about it, to see what excuse he has got; because justification he does not pretend he has got, although he will have to before he is going to get out of this matter. He says it was fair comment—that is to say: "Yours was a fraudulent system of dealing" was fair comment upon this. There was an inquest held, says he; it was proved at the inquest that a man called Cushing was a labourer, and that he had been using an inhaler for which he gave three guineas, and a fluid for which he gave eight shillings an ounce; that he was suffering from advanced consumption, and that the coroner said that he had had a number of cases where the people had been deceived by the Government stamp upon proprietary articles, and that the Government ought to stop it because it deceived people into supposing, which was not the fact, that the Government gave some sort of voucher for the value of the article on which the stamp was. Then he goes on to speak of the other matter which was outside of the *inquest, that the* plaintiff sells the inhaler and the specific at the price at which he in fact sells them, and that other people who may be rascals for all I know—I am not going to try their character—other people of whom he has given us a tremendously long list, who advertise in the papers all sorts of remedies—I am not going to mention one of them—which have all sorts of *notorieties—that* those people are fraudulent quacks. You follow that my client's apparatus and liquid are expensive, and other people publish fraudulent advertisements of quack medicines; and then he says: If that is true, if Cushing did in fact die of consumption after he had been using your asthma specific for about two years, and if he in fact paid the price we mention for it, and if the coroner said that the use of the Government stamp deceived poor people and ought to be stopped, and if you do sell this stuff at a high price whereas the ingredients could be bought at a low price, and if other people publish fraudulent quack advertisements, then we, the proprietors of THE LANCET, are entitled to say about you, the *plaintiff, that you* carry on a fraudulent business, you rob, you poison the public, and to hold you up to odium in that way. Anything less like the charge they made than the materials upon which they sought to justify it would be hard to see. I venture to say that it would be *impossible that a charge* of carrying on a fraudulent business by fraudulent dishonest methods could be supported upon what is suggested to have *taken place* at this inquest and what is suggested to have been said by the coroner.

It may be these defendants, if they go so far, will call the coroner. I desire to speak with respect of every man who holds a public office in this country. For my part I cannot imagine that any coroner, whether in London or in the remotest part of England, who was inquiring into the death of a man who *died of consumption,* could have felt himself justified, in the absence of some other man about whom he knew nothing, in declaring that he found *that other man* guilty of being a fraudulent rascal, carrying on a fraudulent business, and robbing and poisoning the public. I cannot conceive that any coroner would forget the instincts of judicial office—a minor judicial office—or the instincts of *fair play among men, so far as* to say such a thing as that about a man whom he had never seen, with regard to a specific of which probably he did not know, under circumstances which were not before him for trial; but we shall see. I say that because the defendants, not being apparently satisfied that the pretended defences which are set up in what I have read to you would clear them of the attack of which they had been guilty towards the plaintiff, on Nov. 21st last, after a lapse of four or five months, in which they could *make honest and patient and unprejudiced inquiry,* and could find out whether the man carried *on his* business as a respectable firm of solicitors had told them he did carry it on, by this method of not selling these articles except upon trial, or at any rate offering them for trial in order that people might know what they were *doing*—after having four months for ascertaining that, I will tell you what they did. *They did not* amend their defence by saying that they regretted they were wrong, or by saying they found they were right, and that the plaintiff did carry on a business by fraudulent means. No, they added a little more venom to this pretended plea of fair comment—a plea which was an abuse of the right of pleading, a plea of matters which if they were to be pleaded to attack the plaintiff's character ought to be pleaded as matters of fact and not as matters of statement in the plaintiff's absence. But they went on to add that the plaintiff's specific was used by Cushing according to the plaintiff's printed directions—that was harmless enough—and that the coroner said "Tucker's asthma specific appears to be an American thing. ...... Gentlemen, this is what I call a quack remedy. ...... Anyway, *gentlemen,* the remedy is a fraud." Four months after they had delivered their defence and seven months after they had published their libel they said they had discovered that the coroner had said that this was a quack remedy and that the remedy, meaning Tucker's asthma specific, is a fraud, and then they *left* it there. They do not venture to say: *This* is a pretended remedy, it is *spurious,* it is ineffective, or anything of that sort; but they say that the coroner said this. They cannot shelter themselves behind the coroner. They have said: "You, Tucker, the plaintiff, carry on a fraudulent system of business." That is one thing they have said, and they have said these other matters and they *cannot shelter* themselves behind such a statement as that, if it was ever made, which I take the liberty of doubting, if it was ever made by a person who had no right to make it, because he had not had the people before him upon whose conduct it was suggested he proceeds to pass this severe censure. But that is the way in which they have left it, and so they say that if the coroner in fact said that this was a *quack remedy and that* he regarded it as a fraud, if he said that in his privileged position—rather, I think, by way of abuse of a privileged position, but that is beside the mark—if he said that then we, the proprietors of THE LANCET, are entitled to take our newspaper and to publish to the medical profession among whom you have numerous customers, that you, Tucker, who deal in England in this remedy, carry on your business by a fraudulent system of dealing, that you are the representative in England of a man who is a quack—*that* is, this medical man in America—and that your remedy *itself* is a quack remedy and a fraud. If they think *they* can shelter themselves behind anything, whether it was *said* or it was not said, or behind the coroner, they will find themselves, I believe, grievously mistaken *before* they have done with this case. But upon those issues they have *left this case to be tried.* They have taken care to avoid giving Mr. Tucker an opportunity of *dealing* as he would have been glad to

TUCKER *v.* WAKLEY AND ANOTHER.

IN the High Court of Justice, King's Bench Division, at the Royal Courts of Justice, on Wednesday, Jan. 15th, before Mr. Justice RIDLEY and a special jury, the case of TUCKER *v.* WAKLEY and ANOTHER came on for hearing. Mr. H. E. DUKE, K.C., and Mr. F. E. SMITH (instructed by Messrs. F. VENN and Co.) appeared for the plaintiff. Mr. J. ELDON BANKES, K.C., and Mr. HUGH FRASER (instructed by Messrs. POTTER, SANDFORD, and KILVINGTON) appeared for the defendants.

Mr. F. E. SMITH opened the Pleadings.

Mr. DUKE: May it please your lordship, gentlemen of the jury: As you have heard from the opening of the pleadings by my learned friend, this is an action brought to recover damages for a libel published by the defendant in his newspaper of the plaintiff in regard to the plaintiff's business and with regard to the plaintiff's character—of his business and as a man. The plaintiff has been carrying on the business, which I will mention to you more particularly in a minute or two, in London and throughout England for now something like eight or nine years. He has carried it on as he and his customers, I think you will find, thought reputably; he has carried it on with very considerable profit to himself, and he has carried it on, as I think I will satisfy you, beyond any sort of question, with very great and conspicuous benefit to people who have dealt with him—not to a few people but to great numbers of people, and, as you will see, if those averments are true with regard to the plaintiff, it is an exceedingly serious matter that he should be publicly accused of selling a remedy which is a fraud and selling it fraudulently and being a man whose dealings are fraudulent dealings. Those are the charges, with other charges, which the defendant, who is the registered proprietor of THE LANCET newspaper, did not hesitate, now many months ago, to launch against the plaintiff without, so far as I am able to see, any knowledge of what the plaintiff's remedy was; without any knowledge, so far as I am able to see, of what the plaintiff's mode of business was; without any knowledge of whether his business was honest or whether his remedy was beneficial. The defendant having made those charges in his newspaper, launched so long ago, has followed them up and persisted in them, and he is here, as I understand, by his counsel, and I suppose, by evidence, to seek to justify himself in what he has done. THE LANCET, as you know, gentlemen, is what is called an organ of the medical profession. It is a newspaper very well known, and, I should say, in the general way very well conducted. It deals with subjects of medical science and it deals also with the professional and class interests of doctors, as a profession and as a class, and their substantial and pecuniary interests. It is warranted in protecting those interests by every legitimate means, and you will have to ascertain in the course of this case whether there can be any sort of warranty in the championing of the professional and class interests of any profession, no matter how eminent, in dealing with a man who deals in a remedy in the manner in which the plaintiff in this case has been dealt with. I shall have to tell you something about the commodity the plaintiff sells. He sells it merely as a commodity; he does not pretend, and has never pretended, that he was the inventor of it, or that he is a man of medical skill, or that it is anything else than a specific for the treatment of a well-known specific ailment. It is a specific for the treatment of asthma. I daresay all of you have either experienced in yourselves or in your families, or have seen in other people, the disease of asthma. It is a paroxysmic disease which attacks the respiratory organs suddenly, or with some little warning, which disables the patient while the paroxysm lasts, and undoubtedly weakens his system and becomes chronic and is a source of very great misery and suffering to people who are subject to it. It is a well-known and perfectly specific ailment, with well-known and specific symptoms, an ailment which I think we all know is generally treated by something rather in the nature of mechanical than medicinal means—the inhalation of some sort of remedy. These are matters of common knowledge. I daresay you are well aware that in some cases powders are burnt and the patient inhales the fumes of them to arrest the spasmodic operation of this ailment. In other cases cigarettes of a herbal character, datura stramonium, are smoked by the patient. I mention these things because we all see them in every-day life if we happen to come into contact with persons who are suffering from asthma. Those are the kind of remedies which are well known. With regard to those I think it will appear in the course of this trial that medical men fail to deal with asthma by medicinal appliances which go to affect the physical system and the constitution of the patient. I think you will find that the remedy generally has to be some simple and mechanical remedy applied to deal with the symptoms. The remedy in which the plaintiff deals, which he sells and has sold, is a remedy called "Dr. Tucker's Asthma Specific." I will tell you about Dr. Tucker presently. He is the brother of the plaintiff, a medical man of good position and repute at Mount Gilead, Ohio, in the United States. I will tell you presently how it comes that this remedy is in existence and in use, but that is the name of the remedy, "Dr. Tucker's Asthma Specific." It consists of a liquid and a vaporiser for the purpose of converting that liquid into vapour which the patient can inhale through the nose into the throat and lungs. I think I mentioned to you that Dr. Tucker, who discovered the proper ingredients for the liquid which is here in question, is himself a physician and the brother of the plaintiff. The plaintiff will tell you that Dr. Tucker, after he had entered upon his practice as a medical man, found himself subject to repeated and distressing attacks of asthma to such an extent that he was not able to carry on his practice continuously, and that Dr. Tucker thereupon applied his knowledge and skill towards the endeavour to discover a remedy for his own treatment in order that he might live the life of an ordinary professional man and not be disabled by these spasmodic attacks of asthma which continually came upon him, and he produced the liquid which is here in question. There are matters in regard to the composition of that liquid which are raised upon the pleadings in this action and which I will mention to you presently. They seem to me to be wholly irrelevant to the gross and grave charges which this defendant has thought fit to launch against the plaintiff, but as they are put upon the pleadings I shall deal with them in their order. I may say to you now that the plaintiff himself has no personal knowledge of the constituents of that liquid and he has never sought to ascertain. It was not his business to know. As to the other item in the treatment, the vaporiser, that is an article of a not unusual kind, but a very efficient article of a not unusual kind. I dare say you know that by applying a blower of some kind to some tubes in connexion with a bottle you are able to produce a spray. In this case the vaporiser and the inhaler is not an article which produces a spray. A spray which is injected into the air passages and falling into the lungs would cause distress, probably, and not relief, according to one's ordinary notions of the mode in which you can deal with the lungs. This is a vaporiser and not a spray-producing apparatus. It is produced by a firm at Boston, I think, in the United States, appointed and employed for the purpose by Dr. Tucker, the plaintiff's brother, and every one of the vaporisers is examined by Dr. Tucker himself and examined also by the plaintiff, who has a great deal of practical knowledge of this apparatus. It is quite a common-place apparatus in its way. Its particular value arises through its particular efficiency from the care with which it is manufactured and with which it is inspected. Here you have it (producing same). A vapour arises, which you cannot see probably. Two or three compressions of the bulb here discharge a body of vapour which is produced from the liquid in the bottle.

Mr. Justice RIDLEY: Those are very common things.

Mr. DUKE: Very common things indeed.

Mr. Justice RIDLEY: I can get it at a chemist's shop. I have one in my room at the moment, not like that, but a simple one that I was ordered by the doctor when I had a bad throat.

Mr. DUKE: That is probably called a spray.

Mr. Justice RIDLEY: Yes, I think it was called a spray. You fix it into a bottle.

Mr. DUKE: That is the type of thing which produces a spray. This apparatus produces a vapour which is intended not to be deposited on the throat in the way a gargle is, but to be inhaled into the lungs.

Mr. Justice RIDLEY: The one I had was fixed into a bottle containing the liquid.

Mr. DUKE: Yes; that is done here. Your lordship can

Mr. Justice RIDLEY: That was an instance which came under my observation; I daresay there are others.

Mr. SMITH: Your lordship will hear evidence, no doubt.

Re-examined by Mr. SMITH.—I understand that in your pre-Tucker days, if I may so express it, you had several poisons recommended to you by the medical faculty?—Sir William Jenner fed me mostly on arsenic and other doctors have given me chlorodyne. I could not tell you the name of any doctor who has given me that, but I believe chlorodyne is mostly laudanum.

Mr. Justice RIDLEY: But although they are poisons, in minute quantities they are perfectly well recognised by doctors; so is strychnine.

Mr. SMITH: Yes, so I understand.

Mr. ELDON BANKES: Yes.

Mr. Justice RIDLEY: That is the poison which is in Fellows's syrup.

Mr. SMITH (to the Witness): As for cocaine, I will just ask you one question. Was cocaine prescribed to you for asthma or not?—It was a suggestion which a doctor once made to me for hay fever as a relief.

It was rather suggested by my learned friend that you showed some unusual degree of care in your use of this atomiser; was that so?—Absolutely no.

Is it an instrument which it is easy to use either with great care or with negligence?—I should have thought you could only use it in one way, and it could only be a question of the amount of use, and I have never shrunk from using it as often as ever I wanted it—I mean three or four times an hour.

You might pinch that rubber ball carefully or negligently, but beyond that is there any way of using it carefully or negligently?

Mr. ELDON BANKES: It is a question of frequency.

The WITNESS: I understood the question was a question of frequency, and as far as frequency is concerned I used it as frequently as ever I wished to and I have never exercised the least care.

Mr. SMITH: When you first began to use it in order to deal with these night attacks what was the frequency of the use you had to make, roughly?—It might be three or four times in half an hour or even oftener, but the relief comes so quickly that you do not want to go on using it for hour after hour because, so far as I am concerned, relief always comes very quickly. You would not go on using it for hours because the relief is so quick.

Mr. ELDON BANKES: Unless you have got the cocaine habit.

Mr. SMITH: Is that my friend's suggestion?

The WITNESS: I do not follow that.

Mr. ELDON BANKES: We will discuss it afterwards.

The WITNESS: I have not got the cocaine habit from the use of it so far as I know.

BERTRAM EARL of ASHBURNHAM, *examined by* Mr. SMITH.—Would you mind telling us how old you are?—Not at all; 67 years old.
